Dremel tools are your friend. Use a small abrasive disc wheel.

Good ideas, thanks to Andy and Leon.

I will try to borrow a dremel.

james

I usually use the side of a grinder wheel to cut it off. If I do not have one handy, then I use a triangle shaped file. I often cut it part of the way and then snap it off with the pliers.   It usually takes bolt cutters to cut the antenna and then the cut off piece goes out like a bullet.

Need element length measurements. I have the pdf file from the MFJ/
HyGain web site but some of the measurements are difficult to read.
Fuzzy scan and vision. It is page 5 in the manual, where it shows the
complete layout of the antenna. If someone can make a clear hi-res
scan of this one page and email it to me that would be great. It will
be most appreciated, 73, Randy, w5kcm

That was my spell checker. It never heard of a vise.
Even now it is marking vise in red.

```

Jim,

It cuts a lot like glass rod.   A Dremel is probably the most
civilized way to do it, but I use a small file to cut a shallow notch.
Then, I use a vise or other hard surface to support the long section,
placing the nick right at the edge. A smart blow with a small hammer
will break it off. Use the file to remove the burrs, and off you go.
It requires a bit of practice to get it right, but it works perfectly,
at gets you some appropriate street creds with newer hams.

There are a number of TH-3 versions.(Jr, MK3, MK-IV) Here's a link to
the TH3-MK-IV
py5sg.homeip.net:2000/manuais_e_esquemas/hygain/TH-3MK4.pdf
with a clear page 5.

There's also something wrong with using a "bench grinder".  Why would
you want to grind down the bench?

Please ... treat yourself to your own Dremel. You'll always be glad you did.

I bought my first Dremel under the Wards Powercraft name in the 1970s. I retrofitted it with an Allied Radio Motor Speed Control and used it for decades. A few years ago, when the bearings began to sound funny, I bought a replacement. I will NEVER be without a working Dremel.

I have the additional collets (like the chuck on a drill) that allow me to use tools with smaller shafts (like surplus dental drills) and drill bits of any size, down to a # 80 drill bit. I have many dozens of attachments and even a little Dremel drill press.

> purpose at hand.)

I'll just add the reason -- the common mode current, which is what causes feedline radiation and what we're trying to suppress, is on the outside of the coax. The commonly specified velocity factor (around 0.66 for solid dielectric coax, a bit higher for foamed dielectric) applies to the field inside the coax where the differential mode current flows, not to the outside where the common mode current is. So you use a value near one as Owen says. And it's not at all critical for this purpose.

A standing wave is present on an antenna or radiating feedline -- every half wavelength there's a current null, and offset a quarter wavelength from these are current maxima. For example, there are current nulls at the ends of a half wavelength dipole (or, an even better example, a Yagi parasitic element) and a maximum at the middle. When you insert a balun in a transmission line, it causes a current null at that location, so there'll be a maximum a quarter wavelength down and another minimum a quarter wavelength below that if current is induced by coupling and the length to ground supports that distribution. We want to make that distribution impossible, and inserting the second balun does that.

This is easily observed by modeling, but you have to keep in mind that the actual path the current takes to the Earth along the outside of the coax can be considerably more complicated than most simple models represent. So models can tell you what *can* happen although maybe not necessarily what *is* happening in a given installation.

I've always found that a small set of Bolt Cutters works great....
such as Kobalt 8" or 14" Bolt Cutters $9.98 and $14.98 at Lowe's.

Just one tool to do the job right then and there after checking SWR...

Tom

When I worked in the Mobile radio business as a tech, we used to use a small triangular file. Score the whip with it and then take a pair of lineman's pliers and just snap it off. Quick and simple.

Hmmm you say "ridicuously undersized"..

Why?

have you studied the fusing current of AWG 10?
Have you compared the inductance of various sizes?

Do you know *why* the code only requires AWG 10?

The code requirements are based on actual science, engineering, and test data, so if the code requires AWG 10, it's probably for a fairly good reason.

Note that they allow bronze and copper clad steel as well as solid
copper, so clearly, DC resistance isn't what they're worried about.

(hint.. think of mechanical reasons)

Note, especially, that the NEC (NFPA 70) grounding/bonding requirements
are NOT for lightning protection. (that's in NFPA 780, not NFPA 70)

IIRC the purpose is to primarily drain off the static charges so the
gnd-cloud potential difference is minimized. A direct strike will
usually just melt whole house wiring, etc. etc.

If you want something beyond code typically we use 00 braided copper
at work for lightning protection on towers. NEC and Polyphaser
recommendations usually work pretty good

Not true.

The cloud has SO MUCH charge you don't stand a chance of bleeding it off.

Direct strikes are typically around 20 kA, and can be as high as 100kA. Both can be adequately carried by the usual AWG6 wire, because the current pulse only lasts a few microseconds.

Tom Horne wrote:

> Owen
> Believe it or not the NEC only calls for number ten American Wire Gage (AWG) or 5.261 (mm)2 for protective grounding conductors. Bonding conductors between electrodes are only required to be number six AWG or 13.30 (mm)2. So leaving aside the bad joke that is the NEC requirements I'm trying to get some idea of what best practice might be.

Tom is a bit confused here about the purpose of NEC vs NFPA 780..

The bonding requirements in the NEC are designed to keep the building from burning down in the event of an accidental fault to an energized conductor. The basic requirement is that it carry enough fault current for long enough to trip the overcurrent protection device on the energized conductor.

It's not for lightning protection, per se. (although NEC bonding will, incidentally, provide some degree of protection against induced transients)

I'd also note that AWG 10 wire is more than sufficient to carry a 50kA pulse for the 20 microseconds or so that a lightning stroke lasts without melting.
Using the Onderdonk equation, you can calculate that a AWG16 copper wire will carry about 90kA for a 20 microsecond pulse. AWG10 should be able to carry 4 times that much. AWG6, 10 times, because it scales with cross sectional area.

Having only really paid attention to this recently, I noticed that in Rome (a place with a fair number of thunderstorms), they use fairly small down conductors (AWG 10 or 6, just by eye), and similar for 7 story tall wooden pagodas in Nara, Japan (another place with lots of thunderstorms).

I'm not quite sure where the fashion for 2/0 grounding conductors comes from (maybe Phelps-Dodge has a representative on the NFPA 780 review committee?<grin>)

This is actually a big problem.. counterfeit rods with UL markings on them, and rods that are too small in diameter or too short to meet NEC requirements.

Electrical Supply places (not the home improvement stores) have had 10 foot rods for a long time.

The NEC has required 8 feet *in the ground* for years and years (at least 20, I think), so the only way to do that with an 8 foot rod is to do your exothermic bond to the rod and completely bury it.

The home improvement stores don't like to stock longer rods because most of the buyers are not "code-aware" and buy on price (hey, an 8 foot rod is cheaper than a 10 foot rod, I'll use that). Besides, for new construction in a lot of places, a rod isn't an acceptable primary grounding means anyway.

And we won't even get into the grounding/bonding practices of satellite dish and Cable TV installers.   There's a great website out there with pictures of truly lame installations.

NFPA 780, like NFPA 70, is a copyrighted document *sold* by NFPA.
However, there *are* online copies of various provenance and age around.
http://www.atmo.arizona.edu/students/courselinks/spring07/atmo589/articles/
NFPA_780_2004.pdf

Unfortunately, the bare code doesn't tell you much about the "why" for various code provisions, so if you're thinking of going "off code" for one reason or another, you don't have a lot of information to tell you whether it's a good idea.

There's also some interesting seeming inconsistencies.. NFPA 780 requires a minimum length of a ground rod of 8 feet (4.13.2.1) but also requires that they extend vertically not less than 10 feet into the earth (4.13.2.3(A))) The figure makes it clear.. the top of an 8 foot rod is 2 feet below the surface of the soil.

NFPA 780 says 29 square millimeters for main conductors (6 mm in diameter or a strip that is 1.3mm thick x 22.3 mm wide).. That's AWG 6 roughly.

There's also a great site by Carl Malamud: publicresource.org that has all the California Building Codes (including an older rev of the NEC) although it doesn't have NFPA 780 on it, as far as I know.

Perhaps you could explain why you think it's a bad joke? Do you think a
13 square mm conductor couldn't carry the strike current? (it can)

Or, perhaps, you're thinking that there are some other design criteria
that might push one towards a larger conductor (mechanical strength in
the face of icing and storms might be one).

On the yard around my house I have two possible spots where to erect a
multiband vertical, an HF6V.
On the first spot it is possible to lay down a symmetrical net of
radials as long as the antenna is tall, but the antenna will be close
to buildings on tree sides, at a distance about two to four times the
antenna height. Buildings in Italy are built by rinforced concrete
with a lot of steel inside, so I expect there will be some effect to
the antenna efficiency and radiation pattern.
On the second spot, the antenna can be more clear of buildings, but
the radials pattern is not symmetrical because il is limited to a
strip of land wide half the antenna height.
So now is my question: if a tradeoff must be made, what is more
important, to have an antenna on the clear or to have the best ground
radials system ?
A second question: is it possible to estimate the effect of ground
symmetry and of buildings presence on the antenna radiation pattern
using antenna simulation software like eznec ?

Thanks to all
Giovanni

Resistance isn't actually a big deal here. It's all about inductance on
that microsecond rise time pulse.  And there's not much difference in
inductance between a AWG 6 and 2/0 (it's very weakly dependent on
diameter and strongly dependent on length.. 1 microhenry/meter is a good
```

estimate, pretty much independent of diameter)

The other problem is that for fast transients, skin effect means that the AC resistance goes more as the diameter than as the cross sectional area (hollow tubes work just as well as solid conductors).

So, the net effect is that you need to design for several things:
1) the wire not melting..
2) The wire not breaking from mechanical impact (ladders hitting it, lawnmowers, etc.
3) The wire not breaking under electromagnetic forces (this is why you don't want loops and why NFPA 780 says 8" bend radius.. while a 1 microsecond pulse at 10kA won't melt a AWG 10 wire, if it's in a loop, it will destroy it from EM forces)

You'll see heavier conductors where they have to be able to move (say on a gate or actuated device), not only for mechanical life, but also because the flexible wire is more subject to destruction by EM forces.

Side flash is a consideration, but usually accommodated by making sure your downleads are far from potential victim circuits.

That's why I tie everything together. In my case, the ground rods
are minimal.. Just a few copper tubes pounded into the ground
around the base of the mast. None are too deep. But I consider
the ground adequate for the purpose, and it seems to be, being
as I've taken strikes on that mast with no damage to anything.
But I tie that ground into the electrical ground, and also the
plumbing, which I clamp to just a few feet away from the base
of the mast. If all grounds are at the same appx potential, and
the connection to ground is up to par as far as resistance, you
shouldn't see flashing over to other objects. I've never had that
problem here so far. In fact, the connection to ground seems
good enough that strikes to that mast are fairly silent and
only make an electrical arc sound which sounds like throwing
a light bulb onto the ground.
On the other hand, a strike to a poorly grounded object with
high resistance is hugely loud.. Say when it strikes the tree
in the front yard.. It's like a 12 gauge going off. And this
sound is separate from the sonic boom of the strike as
it travels through the air. The sonic boom will come from
overhead and is not local like the actual strike noise at the
object being struck.

better to have the radiating part of the antenna clear. The ground
radials, as long as they are numerous, are less critical

> A second question: is it possible to estimate the effect of ground
> symmetry and of buildings presence on the antenna radiation pattern
> using antenna simulation software like eznec ?
>

Yes.. to a certain degree

What you can do is put in wires where the building is (like a wireframe
drawing), and then see if there's very much current in those wires, when
the antenna is excited. Small current = little effect.

You can get fancier and try and model the building as a grid of wires which are very resistive, but I'd start with the simple wireframe and see what it gives you.

What you're really getting isn't a precise model, but more of a qualitative assessment of whether there is a problem.

>important, to have an antenna on the clear or to have the best ground
>radials system ?

Hi Giovanni,

The best solution is both - in the clear with a lot of radials. The next best is to raise your antenna, if you can. After that, and assuming the antenna is ground mounted; then use as many radials as you can (12 or more); as long as you can make them (usually as long as the antenna is tall is enough); filling as much area as you can.

Multiband verticals are usually designed to be up at least 3 meters.
Multiband verticals are usually poor performers on their lowest band.

>A second question: is it possible to estimate the effect of ground
>symmetry and of buildings presence on the antenna radiation pattern

>using antenna simulation software like eznec ?

Yes. Do it one band at a time to keep it simple. You will be able to see the effect, but it won't really amount to much UNLESS you are comparing very few radials (2,3 or 4) to 12 or more; or to 120. The change from 2 to 12 will be more significant than changing from 12 to 120.

You will also see the change in shape of the antenna pattern's azimuth. It may seem significant, but in reality, it will be overshadowed by other effects like the proximity of buildings.

Modeling the effect of buildings takes a lot of time and experience. Antenna modelers are an extension of your design capability, not a substitute.

On Jul 7, 6:14=A0am, Keith Dysart <keith.dys...@gmail.com> wrote:
> As i pointed out, the energy levels are well above the noise.

You have certainly not proved that to be true. The current is essentially DC for most of the year. Therefore, you cannot assume the proof to the question of whether the photons, which may or may not exist, are above the noise level. (Hint: assuming the proof is one of the most well known logical diversions.)

What I said was that one photon at 0.5 cycles/year is NOT above the noise. You are free to try to prove that I was wrong. If you window your signal for 1/2 of a year, I believe you will find it to be DC steady-state. I do not believe it is far enough removed from DC to generate any detectable photons.

I will be away from my computer for a few days. In the meanwhile, I suggest that you prove that a conservation of power principle exists and a conservation of current principle exists. Until you do that, you are just blowing smoke. But it you succeed, you will no doubt receive a Nobel Prize.

```

Over the years I have seen many patterns for horizontal dipoles and the inverted V antennas,but do not recall seeing any V shaped patterns in the books. That is a dipole that is supported on the ends, but sag in the middle.   I know the sag is needed to some extent because of the weight of the wire and feedline, but what happens to the pattern if it is say 1/2 wavelength or 1/4 wavelengths at the ends and the sag in the middle is changed. Maybe drop it a few feet, then 10, 15 and 20 feet for 80 meters.

I know that for maximum distance you usually want the high current portions up high,but maybe it will be better as a close in or omnidirectional antenna if the center is lowered somewhat.

In EM current is incompressible. EM is older then electrons.
"charge can be stored" apply to electrons. It is impossible to marry EM and
electrons.

>Until you can prove a conservation of current principle, you are
wasting my time.

"According to theory" a conservation of current principle (continuity
equation) is the assumption.

In EM is the displacement current in solid insulators (also in vacuum). It
is always incompressible because the motions of the particles are
synchronized (charges can not be gathered).

EM is beautiful but useles in techniques. It is  useful to teach the math.

Yes, very interesting example (and device),

Cecil it is right respect a photon/noise power ratio, even one photon
of 80 m per second it is very below of noise at 1 K, 80 m-quantum/
Noise dB ratio @1 Hz BW =3D -38 dB.

Respect to DC current EM radiation, In that time Richard bring an
interesting example of 20 kV electron rectilinear beam rendering a
frequency of 34.6 EHz, the calculus it was quite right, but that
frequency it is not EM waves radiated by electrons but a "matter wave'
frequency... (idem with car analogy =3D> not charged and acelerated
```

cars :>) do not radiates EM waves, but may have a matter wave asociated to them).
For these reasons IMHO I think -as Cecil do-: basic (undergraduated?) physics books are very useful to helping us to better understand and enjoy our ham topics.

Ralph Mowery wrote:
> Over the years I have seen many patterns for horizontal dipoles and the inverted V antennas,but do not recall seeing any V shaped patterns in the books. That is a dipole that is supported on the ends, but sag in the middle.   I know the sag is needed to some extent because of the weight of the wire and feedline, but what happens to the pattern if it is say 1/2 wavelength or 1/4 wavelengths at the ends and the sag in the middle is changed. Maybe drop it a few feet, then 10, 15 and 20 feet for 80 meters.
>
> I know that for maximum distance you usually want the high current portions up high,but maybe it will be better as a close in or omnidirectional antenna if the center is lowered somewhat.
>
>

In free space, there is not much difference in pattern between a dipole that is perfectly horizontal and one that is drooped or sags (or for that matter one that is bent horizontally). What changes is the feedpoint impedance (72 ohms for perfectly flat, getting towards 50 ohms with a 120 degree included angle).

The other thing that changes is the apparent height above ground. If you model a drooped dipole and fiddle with the height to try and match the vertical pattern for a perfectly flat dipole, you find that the "effective center" of the drooped dipole is around 1/3 of the droop distance. That is, if you had a dipole where the center were at 100ft, and it drooped 30 feet on either end, the pattern is about the same as a flat dipole at 90 ft.

The height above ground has a HUGE effect on the dipole pattern (especially at low elevation angles) and probably dominates any small changes.

After all, a perfect dipole has a gain of 2.15dBi and a infinitely short dipole has a gain of 1.6dBi, and a drooped or sagging dipole pretty much has to be somewhere in between.

Those gains are for dipoles in free space. A dipole over ground typically has several dB greater gain.

The absolutely worst gain any efficient antenna can have in free space in its best direction is 0 dBi. So nothing you can possibly do to the pattern can reduce it below this value in free space, as long as you don't introduce loss. But as Jim says, you can mess with a dipole a fair amount without changing the pattern much -- except for filling in or moving the nulls, which can be very sensitive to small changes.

This is foooooo amusing.

You refuse to start to examine the proof because it has not yet been
proved ... which can not happen until you examine the proof.

You are truly amazing at developing mind stopping techniques that
inhibit your ability to learn.

...Keith

Of course, there are many photons in the 50W signal previously
mentioned. That is the only way to get to 50W.
```

> You are free to try to prove that I was wrong. If you window your signal for 1/2 of a year, I believe you will find it to be DC steady-state. I do not believe it is far enough removed from DC to generate any detectable photons.

> I will be away from my computer for a few days. In the meanwhile, I suggest that you prove that a conservation of power principle exists and a conservation of current principle exists. Until you do that, you are just blowing smoke. But it you succeed, you will no doubt receive a Nobel Prize.

Ahhm, so you are proposing a new concept: a lower frequency limit where a sinusoid stops being an EM wave and becomes what? Slowly varying DC?

I have never seen such a concept mentioned previously. Perhaps it will be you who deserves the Nobel prize.

At what frequency, approximately, is this limit?

Or, if that is not yet known, what is the lowest frequency that you are currently convinced would be an EM wave, such that the cutoff must be less than this frequency?

Ballpark is good:
  1 MHz
  10 kHz
  1 kHz
  100 Hz
  10 Hz
  1 Hz
  0.1 Hz
  0.01 Hz
  0.001 Hz
  1 uHz
  1 nHz

Just to the nearest order of magnitude, from the above list, which frequency are you sure is still an EM wave rather than slowly varying DC?

I am pretty sure that you would accept 10 kHz as been EM. Omega used to be around 10 kHz.
How about 60 Hz? This is standard AC power in some jurisdictions.
25 Hz used to be common as AC power.
10 Hz? Is the audio on its way to the woofer an EM wave?
1 Hz?

Just an order of magnitude frequency that you are sure your EM cutoff frequency will be below.

And how much above the noise does a photon have to be for

you to consider it to be a photon? Perhaps this will help you
choose your cutoff frequency, though it seems to me you will
have some difficulty when there are lots and lots of photons
at this low frequency. Will this not be adequate for detection?

By the way, is it possible to detect a single photon at 10 kHz,
a frequency which I am pretty sure you would consider to be
an EM wave.

Sure. You described charge flow in and out of an isolated node with no
need to reference any other node or part of the circuit. Then you say
the same thing can be defined for energy. However, how is energy defined
in terms that only refer to characteristics of the node without
involving any other part of the circuit or other nodes.

That has absolutely nothing to do with the quality of the persons work. If they no longer enjoy it, and many never did from the start, they chose the wrong field. Generally when a person becomes bored with their work, or dissatisfied the quality of their work suffers. With nearly 35 years of working I saw a lot of that.

If you are a professional who is bored out of their mind, quitting and going back to college to pursue a different field certainly is an option.

That is what I did after working over 26 years.
I originally enjoyed the work and had fun on the job. Did that make me an amateur professional? I chose the line of work because I loved doing it. OTOH there were those who figured I must not be doing my work because I appeared to be having "too much fun". After changing professions and jobs I ended up working for and with people who were not so narrow minded and understood. When I retired it was as a project manager with good people working for me and good bosses above me.

I still loved the work, but I had reached the point where I was seeing too many people working until they dropped at work, or retiring and dropping within a month or two. OTOH I saw more than a few who didn't know any thing other than work. I decided I wanted to go play.

I also love retirement (does that make me an amateur retiree?) , but it could pay better.
>
>Can there even be such a thing as an amateur soldier?

Sure...they don't last too long though.

That is why we have "project Charters"  The "Charter" describes the
project goals and how to determine when those goals have been met.

Any change in goals, or how to determine they have been met means
going back and rewriting the charter and then having all involved
reauthorized it.

My standard replay when some one asked if we could do something with a
project was "is it in the charter?". If not they had the option of
getting the heads of all the involved departments and often "sites" to
review the project charger.  That usually minimized attempts to expand
projects beyond their original design. It also give all involved the
desire to put everything on the table at the beginning. <:-))

I really don't see it in that light. To me there is no higher rank
than amateur. A professional can just be a "grunt", or they can be
some one with goals, or rather "goal oriented".

\>Yes, very interesting example (and device),

>Respect to DC current EM radiation, In that time Richard bring an
interesting example of 20 kV electron rectilinear beam rendering a
frequency of 34.6 EHz, the calculus it was quite right, but that
frequency it is not EM waves radiated by electrons but a "matter wave'
frequency... (idem with car analogy => not charged and acelerated
cars :>) do not radiates EM waves, but may have a matter wave
asociated to them).

Each waves are the matter waves. The speed is the particles mass dependent.
So in the wire the sound waves travel with the low speed (medium are ions),
and the electric waves (medium are the free electrons) with the extremally
high speed.

>For these reasons IMHO I think -as Cecil do-: basic (undergraduated?)
physics books are very useful to helping us to better understand and
enjoy our ham topics.

For graduated is the field math only.

I've used a TH-5 for quite a few years. The drain holes should be
down, but if they are no more than 20 degrees off if the disassembly
is difficult as it sounds, I'd simply drill additional drain holes
that would point straight down. The two sets of holes would probably
drain better any way instead of the meniscus stopping the drainage.
Just make sure the new holes are no larger than the old ones. It does
no good to get better drainage if the critters are going to move in.
The drain hole in the matching network for my AV-640 was large enough
for a paper wasp to get in. The virtually packed it with nests. 800
watts on 6 with a KW on HF was enough to thoroughly cook the critters
and mess up the matching.
http://www.rogerhalstead.com/ham_files/AV-640/AV640.htm

The AV-640 is a good antenna. I've been working world wide using it on
40 since mid winter. It leaves a bit to be desired on 6, but I'm used
to a 7L Yagi on a 30' boom at 115'.

Perhaps some examples will help.

Consider the output terminals of a generator to be junction. Then the power delivered from the generator to the junction must exactly equal, at all times, the power taken from the junction by the load, since there is no storage in the junction.

It should be noted that the 'junctions' used for a power analysis are not the same as the junctions used in Kirchoff's current law. The concepts are analogous, not identical.

Another example. In the simple Thevenin generator, the power provided by the voltage source must exactly equal, at all times, the power taken by the resistor plus the power taken by the load. In this example, it is difficult (impossible?) to identify a physical 'junction' where the power must balance, yet the notion is still applicable.

...Keith

Jim,

My simulations, and some practical experience, has found that an included angle closer to 90 degrees yields a 50 ohm feedpoint impedance. These are 'practical' designs, and not in free-space, of course. Is there a reference you can give me that derives the 120 degree 50 ohm result?

Steve

```

Good morning all
I am going to France for a month in October.
Going to take some HF gear with me (FT897D),But I need some sort of Balcony antenna for HF bands (prob 20mtrs would be ok)does anyone have any ideas what i can build or buy for an antenna,with a balcony mount.I am not sure what else we there for me to string up,all I know is that we have a balcony.I did look at the MFJ 1622 antenna,it look like what I am looking

for,i need to be able to pack it in a suitcase some how
Thanks to all who read and respond
Howard

I will leave you with this parting thought. All that you are saying is that the power at one point (special case: away from any energy storage device) is the same as the power at another point in the same wire (special case: an infinitesimal distance away). No rational person would argue with you on that point. However, that is NOT a general case and in no way proves that power is conserved in general. It is simply a special case where there is a one-to-one correspondence between energy and power, something I pointed out earlier.

The throw of a switch can cause power to be created or destroyed. The throw of a switch cannot cause energy to be created or destroyed. That's the basic conceptual difference between power and energy that you are missing. The same thing is true for current vs charge.

In my energy articles, I took advantage of the special case of one-to-one correspondence between average energy and average power. You neglected to do that for your instantaneous power calculations and proved beyond any doubt that power is not conserved. Your own continuity equation posting indicated that you had erroneously omitted something important from your previous calculations.

It sounds like your "junction" for energy analysis is what's called a "port" in RF analysis. If so, it would be less confusing for you to use that term, since "junction" has a different established meaning in circuit analysis.

For some reason, Keith prefers living in the theoretical world rather
than the real world. His idea of reality is what his math model
subliminally tells him to believe. He doesn't seem to know that
reality is supposed to dictate math models, not vice-versa. :-)

P.S. Let's go card-counting.

Signalwise, a 20M hamstick on a visegrip mount has worked ok for me. But
I got way too much RFI into people's plasma and LCD TV sets.

I agree with Roger here. However, there is, for lack of a better word, a forced rigor or discipline that comes from having to make a living at something. A professional who is "making a living at it" has to meet some minimum standard, or they'll be forced to choose another activity in order to keep body and soul together.

An amateur is under no such restriction. So the "spread" in ability/quality/whatever metric is greater on the bottom tail of the distribution for amateurs.

One sees this very markedly in professions such as acting or modeling.

you might be right.

Some NEC I did a few years ago showed about 57 ohms.

http://home.earthlink.net/~w6rmk/antenna/zdipolev.htm

Since Google is my friend... I found:
J. Earl Jones (probably not the actor) had a paper in IEEE Trans on Ant
and Prop (May 1976) "Analysis of the Symmetric Center-Fed V-Dipole
Antenna" shows, in Figure 6, numbers like you report.. At 90 degrees,
somewhere between 40 and 50 ohms, and at 120, a bit below 60 ohms (for
very thin wires.. h/a = 20,000

The same graph shows that the reactance (for a fixed length) also changes, which has the practical implication that the "resonant" length for a V will be different than a flat dipole.

The paper has analytical, models, and actual data in it. He compares the model data to approximations from King.

And here you go for some more data (although this is more like a half rhombic)

The cost of Copper(World wide) hit an all time high about a year ago,
(maybe a bit more) by, IIRC more than rippling, but then dropped
substantially, although not to the original level. It has been working
its way back up slowly.

Another commodity that has skyrocketed is wood. My neighbor did a
remodeling job this spring and saw the price of plywood take a
tremendous jump. Again, this is world wide, not a local or country
wide problem.

The economies of the two most populous countries are taking off at
fantastic rates.  In the next decade India will have more college
graduates entering the middle class than the entire population of the
US.  China has an almost unbelievable housing boom.

Don't expect things to get much cheaper.

Hello Szczepan, good day:

I do not know if I undestood quit right your sentences (we are both
out of our native lenaguage) correct me if I am wrong.

Today we do not conceive unverse as a material thing, then if you want
to say with "each waves are material waves" that all is mater you are
talking with century XIX words/concepts.
However matter waves are not neither mater nor energy waves, they are
"probabilty waves", probability it is not a "thing", it is a
mathematical concept, surely you know that.

73 - Miguel - LU6ETJ

I prefer the term 'port' as well, but for this particular dialogue I
was
trying to emphasize the analogy between conservation of charge and
conservation of energy by continuing with the same terminology.

Unfortunately, it did not appear to help.

From now on, 'port' it is.

I'd just take some rg-58 coax, and some wire and make a dipole.
Then string it up best you can. IE: one leg could be horizontal
stretching into the building along the floor or ceiling, and the other
end could just hang loose vertical from the balcony.
It's only 16 ft a leg for 20m, so shouldn't be too hard to find a way
to
squeeze it in.
A small weight could hold the hanging end down.
Of course, if there is metal everywhere, coupling to the antenna
could be a problem, and effect tuning.

Yup. Monty Python can't compete.

"My brain hurts!", "Mummy, I want more beans!", aren't even close to these guys.

>Hello Szczepan, good day:

>I do not know if I undestood quit right your sentences (we are both
out of our native lenaguage) correct me if I am wrong.

Such as we have more troubles with writting than with understanding.

>Today we do not conceive unverse as a material thing, then if you want
to say with "each waves are material waves" that all is mater you are
talking with century XIX words/concepts.

Some things were discovered before XIX century. Many more after.

>However matter waves are not neither mater nor energy waves, they are
"probabilty waves", probability it is not a "thing", it is a
mathematical concept, surely you know that.

The new concepts are create every day. All must be verified by experiments.

All concepts on "inmaterial waves" was created by scientists who did not
know that in the space is matter.
Ludwig Lorenz know that because he had known what the sublimation is.
"surely you know that" also.

If you accept the matter in the space when you do not need the EM waves and
"probabilty waves".

don't worry about mr. b... he is stuck in the 19th century.  some day
he may discover that some of the fun things they thought about back
then like magnetic vortices and aether were soundly debunked in the
20th century.

My initial EZNEC models of this antenna have not encouraged me to
continue.

In addition to other issues, the pattern tends to be straight up.

I will make certain that any dipoles I put up in the future will have
the center at least as high as the ends.

OTH, I will put on my DO LIST to investigate the characteristics of
turning the antenna on its side. If the pattern merits, I will
consider the matching situation.

Very interesting!

I am in plasma physics. It is in XXI century. It is nothing wrong that I
know that Ludwig Lorenz discovered space plasma in XIX century.

> some day
he may discover that some of the fun things they thought about back
then like magnetic vortices and aether were soundly debunked in the
20th century.

They were debunked in XIX century.
I do not understand why you and some others use still "magnetic vortices and
aether".
Do not you know that the Heaviside equations describe them"

That's likely because the effective height of the antenna is low. A low antenna on 80m means cloud/worm warmer. (and low, in this context, means <20m, which is still way up in the sky).

So the traditional single support inverted V has all sorts of advantages:
only one support needed
puts the important part of the antenna (the middle) up high

They were debunked by Royal Society. Some years after that Heaviside
reworked them. Royal Society did not accept Heaviside. Now people write what
they want. Why I should go "study what is currently described" about EM.

I prefer real physics.

For many it is difficult to get an antenna up more than 60 feet. That is close to 1/4 wavelength or less.   My back yard has trees on each side and it was easy to string a dipole close to 60 feet on the ends,but no way to support the antenna in the middle. That was why the question of should I string the dipole as tight as possiable with out breaking or adjust the drop in the middle to some optimum distance for what I want to do. I sort of thought the mort horizontal it is the beter the signal would be at a distance, but there may be an optimal angle to have a 200 to 300 mile antenna.

Hi Ralph,

John's suggestion of using EZNEC in its free version would easily answer all the questions, test all the assertions, and find all the unstated characteristics in one fell swoop. It would also let you find the necessary attributes to obtain your goal.

EZNEC would do all this faster than the 12 blind men trying to describe an elephant.

However, as for your several questions above. You are not going to discover gold at the end of the rainbow by tightening the droop. In fact, getting it to an optimal height (as has been hammered home several times as a principle necessity) won't budge your distant contact's S-Meter more than a couple dB (about the width of the needle).

If it causes you pain I'd suggest filtering this thread out.

If you don't know how to do it I'm sure someone here would help you.
They are incredibly helpful.  When they agree on something.

tom

Here's my wild guess as to what's happening, borrowed from my posting in ba.internet and alt.cellular.attws. Apple announced that there's going to be a press conference on Friday, where they'll announce something. Note that I goofed on the location of the wi-fi/BT antenna, but I'll leave the mistake here for now.

On Wed, 14 Jul 2010 13:05:27 -0700, AES <siegman@stanford.edu> wrote:

>active circuitry still works OK?

Nope. My wild guess(tm), based upon what little I can extract from the FCC ID page and from the iFixit autopsy, is that something drastic is happening in receive. The -30dB (that's 1000 times drop) in signal appears in receive, when you're NOT making a call and the xmitter is inactive. Well, the xmitter is sending keep alive bursts every few minutes, but nothing more. Methinks it's a receive problem, not xmit.

I'll go out on a limb and suggest that the receiver front end (probably a GASFET or HEMT) might be a bit regenerative (border line oscillatory). This gives it lots of gain, but only if nothing else changes. In effect, the antenna becomes part of an oscillator circuit, where the oscillatory conditions are partly provided by the antenna Q (i.e. antenna efficiency).
<http://en.wikipedia.org/wiki/Regenerative_circuit>

Touch the antenna, and you reduce the antenna Q. The front end stops acting regenerative (barely oscillating), and the sensitivity drops like a rock. It's the only explanation I can conjure the will cause a -30dB drop in received signal. It's been demonstrated (by me and others) that strangling the antenna of other cell phones drops the rx signal up to -10dBm (10 times drop). That's what I would normally expect to see from touching a cell phone antenna. However, the -30dB drop of the iPhone 4 requires some extra circuit design screwups. Unfortunately, detecting the regeneration is going to require internal probes, test fixturing, and plenty of expensive test equipment.

There's another related possibility. Most of the finger tests have been with the finger bridging the gap. That means they're touching BOTH the cellular and wi-fi/BT antennas. It's obviously the hot end of the cellular antenna, but I can't tell if it's the hot end or ground end of the wi-fi/BT antenna. If the hot end, another possibility it that coupling to the 2nd antenna causes this antenna to radiate into the case, thus causing the cellular front end to oscillate. If the oscillations are bad enough, the signal level will be high enough to induce blocking (overload) in the cellular front end. This can be easily detected with a spectrum analyzer probe in the vicinity. If touching/bridging the antennas causes a new signal to appear on the SA, that's the problem.

It would be very interesting to know if touching ONLY the cellular part of the antenna (the part that goes up the side of the phone), and not the wi-fi/BT antenna (bottom of phone), causes the same drop in signal. It would also be interesting to test the wi-fi signal strength to see if it's effected by touching its antenna.

I have a few other guesses, but these are the best I can currently conjure at this time.

>[I'm an EE, but with no RF circuitry experience, much less any cellphone
>experience. So, I can understand this happening with an active
>transmitting circuit -- though I have somewhat more trouble seeing how
>it would interfere in such a sensitive way with a passive receiving
>antenna.]

Think regeneration and borderline oscillation.

The bad news is that if Apple stabilizes the rx front end, and eliminates the oscillation or regeneration, my guess(tm) is that the resultant phone is going to have a serious rx sensitivity problem. If you look at the cellular antenna in the iPhone 3G and other internal antenna cell phones, they're not very simple looking devices. Lots of strange lumps, traces, pads, and oddities, all designed to optimize performance in the 800/900 and 1800/1900 MHz bands. Getting them to look like 50 ohms for minimum VSWR is also important. Lots of articles in the IEEE Antenna and Prop proceedings on the topic of cramming a dual band antenna in the smallest possible package.

On the other foot, the iPhone 4 antenna is crude. As far as I can tell from here, it's a crude monopole (single wire) antenna. There's no matching circuit for VSWR reduction, and no attempt to optimize performance in the desired bands. I might have missed something in the dissection, but all I can see is an end fed monopole, without a counterpoise or underlying ground. Such an antenna is going to have resonances at odd frequencies, and miserable antenna efficiency.

Disclaimer: I haven't found anyone willing to let me tear into their iPhone 4 yet, so all the above is guesswork.

On mine the top is against your ear and the bottom against your cheek
or upper jaw bone and I'm keeping it until it dies, but those kind of
gadgets have a rather limited life around me. I just want a phone with
voice mail. I have a camera thank you, and it doesn't have a tiny
crappy lens that makes anything much over 1 megapixel nothing more
than bragging rights. I don't want texting, The only thing I need is
the ability to call and be called. I don't need a PDA either.

Even in the old days when we had to use the day planners and even go
to school on them, after the class I dumped everything out of it
including the calendar and picked up a new interior from the stock
room. Threw out every thing I didn't need and used it for a note book
at meetings. To me a day planner would be about as useless and my
profession was a computer systems project manager up until I retired.
It's also my degreed field.

Hi Jeff,

Regenerative designs inhabit the naked edge of amplification/oscillation. You've already said as much. It has to be, thus, a design feature and not a hack. Otherwise every third one is going to break into oscillation and the FCC (or test lab) would have certainly picked up on that. Further, if it is designed in, you can observe that in the design. Special testing methods are too elaborate to explain this. Regen is not a design feature left to the vagaries of production variation in parasitic coupling.

If I'm wrong and Apple does use parasitics to encourage regenerative feedback, then they may introduce a lanyard for hanging the phone around the neck and call it the lavaliere option. No doubt they will sell plenty of mirrors to see it, and someone will come out with an image reversal app. Can a stylus be far behind? Whoops! It will have to be chopstick for squeezing and expanding images.

I note some variation in the use of the term 'Radiation Resistance' (Rr) that suggests that it has different meanings to different folk.

One suggestion is that it is the resistance seen by a transmission line connected to an antenna that expresses its coupling to distant regions of space.

If that is the case, Rr would not capture energy that is lost in reflection from real ground. So, Rr would be the sum of power in the far field divided by RMS current squared.

If indeed it is the "resistance seen by a transmission line", then the current above would be the current at the end of the transmission line.

Does the term have an accepted single clear meaning? Is the above correct?

Some implications of the above are that:
- Rr of a horizontal half wave dipole with zero conductor loss, above real ground, would have Rr less than R at the feedpoint by virtue of some loss in waves reflected from real ground;
- Rr of a half wave folded dipole of equal conductor diameters would be around 300 ohms.

Thanks
Owen

Hi all

I have just modelled both the Slim Jim antenna and J Pole antenna using MMANA-GAL at the same frequency (145MHz) all other parameter equal and was some what surprised that they appear exhibit the same gain and radiation

pattern. Based on an article I read in a English magazine many years ago I
have always believed the Slim Jim had a slight edge over the J Pole.
Wonder if others had a similar view and if my modelling is correct are there
any advantages with the Slim Jim design?

Hello, and I don't find any ambiguities in any of my various EM and
antenna theory textbooks. FWIW, from the IEEE Standard Dictionary of
Electrical and Electronics Terms:

"Radiation resistance (antenna). The radio of the power radiated by an
antenna to the square of the rms antenna current referred to a specified
point. Note: This term is of limited utility in lossy media."

So if we're looking at free (in vacuo) space the radiation resistance is simply a "load" resistance component that accounts for where the radiated power goes. The radiation resistance doesn't include any other resistive losses in the antenna structure/proximity operating environment that may also be dissipating source power introduced at the feedpoint of the antenna. An aerodynamic analogy would be the distinction between "induced" drag (the price paid for "lift") and "parasite" drag, which are both components of the total drag.
Sincerely, and 73s from N4GGO,

Some websites indicate that the only significant difference is that the
Slim Jim has a somewhat wider bandwidth. Unfortunately, I can't
instantly find a good reference. Here's one, but not too good.

Owen,

I like the IRE definition, which according to W8JI is: "The total
power radiated in all directions divided by the square of the net
current causing the radiation".

That definition draws a distinction between Rrad and the resistive
component of the feedpoint impedance; it makes the Rrad of a folded
dipole 75 ohms, not 300 ohms; and it avoids some of the errors folk
make in assuming that "folding" a vertical can reduce ground losses.

73,
Steve G3TXQ

Owen
Can I suggest that you look at things differently?
Radiation is created by the acceleration of charge
which effectively that which creates an acceleration of a particle
such as a bullet from a rifle. The reaction to the firing of the
bullet is the recoil
which is considered as the resistance to radiation.
If you expend energy in other places to get to the point of firing
they can only be referred to as losses.
Thus radiation is a point vector and should not be confused by
multiple vectors that create a plasma.
All radiation equations are formed by the use of boundary equations
```

which requires recognition
of vectors or point charge and NOT by acceptance of the term "waves."
As an illustration, a superconductive material has the minimum
resistance possible to ensure the credibility of Ohms law. This
resistance has nothing to do with "dc resistance" because current flow
is at or near the surface because of the destruction of skin depth
resistance phenomina, which also means the cancellation of magnetic
fields.(Not destruction as the magnetic field is transformed into a
energy bank)
Thus ejection of particles can be considered as purely   that of the
displacement current formed.
Expansion of static laws to those of dynamic form
establishes the use of particles with the use of boundary laws
(vectors) together with conformety with Classical laws.
Regards
Art

I doubt they're using regeneration or some such similar scheme (too hard to control for manufacturing variability)..

However,
the idea of self interference is interesting... (e.g. your finger couples the WiFi to the cellular front end, which blocks)

It could even be as dumb as a dc bias shift thing (save a penny by leaving out the capacitor, oops, that removed the DC block)

As far as match goes, in very compact systems, the idea of matching 50 ohms goes out the door unless one of your components happens to be 50 ohm impedance.. It's not like they're stringing together building blocks with SMA connectors inside there.   Lots of these RF circuits are implemented with differential in and out these days, and the Z is whatever it happens to be.

I goofed slightly. The Anandtech article shows -24dB maximum signal loss.

>Regenerative designs inhabit the naked edge of
>amplification/oscillation.

Not designs. I don't think it was intentional. Someone else mentioned that Apple was so much into security on the iPhone 4, that prototypes were tested in a similar case made to look like an iPhone 3G. That implies that there was little field testing in the new case.

>You've already said as much. It has to
>be, thus, a design feature and not a hack.

I beg to differ. Nobody wants oscillatory effects in the front end of their receiver. They're unstable, vary with temperature, are difficult to control in manufacturing, and will probably make the device fail Part 15 incidental radiation test. Designing a front end that's unconditionally stable with any antenna load does not yield the optimum sensitivity. If you want the best performance, amps that are unstable at specific loads will give better NF and gain.

>Otherwise every third one
>is going to break into oscillation and the FCC (or test lab) would
>have certainly picked up on that.

Maybe. However, one would think that someone would have done a field test with the final iPhone 4 and noticed that touching the antenna gap produced a major signal drop. Also, FCC test are not preformed with human hands wrapped around the phone due to the limited supply of dismembered hands suitable for testing.

>Further, if it is designed in, you
>can observe that in the design. Special testing methods are too
>elaborate to explain this. Regen is not a design feature left to the
>vagaries of production variation in parasitic coupling.

That might partly explain why some users claim that there's no call drop effect when they touch the antenna gap. Of course, users in strong signal areas are not going to see a dropout, while weak signal areas are going to be much worse.

Incidentally, when Consumer Reports ran a test with the rubber ring thing, they slipped and didn't have the technician stand in front of the test equipment this time.
<http://blogs.consumerreports.org/electronics/2010/07/apple-iphone4-iphone-4-bumper-case-fixes-antenna-issue-problem-signal-loss-tested-verified-consumer-reports-labs-quick-fix.html>
<http://802.11junk.com/jeffl/crud/iPhone4-cmu200.jpg> (normal)
<http://802.11junk.com/jeffl/crud/iPhone4-cmu200-hand.jpg> (with hand)
It's a Rhodes and Schwarz CMU200.
<http://www2.rohde-schwarz.com/product/CMU200.html>
I'm not familiar with the operation. The "Reported Power" appears to be the signal generator output power (because it doesn't change when the antenna is touched). However, I can't devine what the "Avg" or "Peak Burst Power" means.

Also, note that the difference in (something) between the first photo (+16.4dBm) and the hand on antenna measurement (-11.7dB) indicates a -28dB drop in signal level. Ouch.

>If I'm wrong and Apple does use parasitics to encourage regenerative

>have to be chopstick for squeezing and expanding images.

We'll find out after the press conference on Friday. My suggestion was to ship a rubber glove with the phone. I also suggested gluing a plastic thumb tack to warn against holding it improperly. Also, a low signal warning tone. Others have suggested tape, rubber prophylactic bump guards, duct tape, warning labels, rebates, bribes, and external antennas:
<http://gizmodo.com/5581253/there-fixed>
Unfortunately, that will require running the FCC type certification tests again.

I'm not suggesting they did it intentionally. I'm suggesting that the front end is unstable and that nobody noticed.

>However,
>the idea of self interference is interesting... (e.g. your finger
>couples the WiFi to the cellular front end, which blocks)

I was looking at the FCC ID web site photos again. I can't even tell which end of the antenna is hot or ground, much less where it's fed. If the hot end of both antennas are facing each other, it's certainly possible. However, if Apple did that, they wouldn't need two separate pieces of metal for the two antennas. They could simply declare some point along the frame as being the official ground point, and have the cellular antenna go one direction, and the wi-fi/BT antenna go the other. Because they didn't do that, my guess is that the hot end of the cellular antenna is next to the ground end of the wi-fi/BT antenna.

>It could even be as dumb as a dc bias shift thing (save a penny by
>leaving out the capacitor, oops, that removed the DC block)

Methinks not. The duct tape solution just reduces the effect, not eliminates it. Assuming duct tape to be a good insulator, that would also suggest that it's not a DC effect.

>As far as match goes, in very compact systems, the idea of matching 50

>with SMA connectors inside there.   Lots of these RF circuits are
>implemented with differential in and out these days, and the Z is
>whatever it happens to be.

If you look at the inside photos of the BCG-E2380A on the FCC ID web pile,
<http://www.fcc.gov/oet/ea/fccid/>
(don't forget to include the "-" as part of the product code), there's a module labeled "Acoustic and Cellular Antenna Feed" on Pg 9 and 10.
<https://fjallfoss.fcc.gov/eas/GetApplicationAttachment.html?id=1300576>
There's a coax cable going across the module, which I assume is 50 ohms.
<http://802.11junk.com/jeffl/iPhone4/iPhone4-accoustic-and-cellular-ant-feed.jpg>
It doesn't appear to do any more than connect a tiny coax connector to the RF module on one end, and a gold screw lug to the frame antenna on the other. No matching in between. Due to the coax, someone must think the antenna is 50 ohms at 800/900 and 1800/1900.

I've never seen a differential RF amp in a cell phone. If so, I would expect either a balanced antenna feed, or possibly two antenna connectors.

Disclaimer: I'm doing quite a bit more guessing than usual. Please do not treat the above as authoritive.

I recall reading though Cebik's excellent web pages on J-poles and variants thereof, a few years ago, and his modeling results pretty much corresponded to yours.

Compared to a simple J-pole with the radiating element consisting of a single wire, the "Slim Jim" variant has two parallel radiators (e.g. the two conductors in a twinlead or window-line). The two radiators may or may not be shorted together at the top.

As far as I can tell, electrically, the addition of the second radiator doesn't make much difference in how the antenna behaves. It doesn't change the overall shape of the current distribution curve on the radiator... just divides the current flow between the two wires. Since the current curve shape is the same, and the vertical span of the radiator doesn't change, the gain pattern will be the same.

It does seem to have the effect of making the radiator "fatter", which can both lower its resonant frequency a bit, and make it a bit more broad-banded.

I believe that for most purposes, the two antennas can be considered equivalent - they're both end-fed half-wave radiators, and will have the gain pattern you'd expect from a half-wave dipole. Both are

equally vulnerable to having their patterns disturbed by current flow
on the feedline or the mast, if you don't take some precautions to
isolate these (e.g. via chokes, a half-wave coax balun, etc.).

Consumer Reports to Apple: "You've been served!"

The long and short of it is that Apple treats its product design like
bulimic runway models. It's up to you to see they get as fat as
necessary to live a productive life.

In other words, there's no room left inside the iPhone for an antenna
and it ruins the esthetics for it too bulge. So, if you don't want to
be viewed as part of the pocket-protector crowd, suck up and hold your
phone like Lady Gaga.

The difference is negligible. They both suffer from unbalanced feed
currents and thus feeder radiation. There is or was a commercial
design that attempted to reduce that.

Hmmm. The last statement suggests that, as defined, it is not clear and
unambiguous in the real world because the real world involves "lossy
media".

The "reference to a specified point" suggests that if one gives a value for
Rr, it is necessary to also state the reference point. Is that what it
means?

This is exactly the lack of clarity that is troubling me.

> So if we're looking at free (in vacuo) space the radiation resistance is

This does not address the issue of ground reflection that I mentioned.

> An aerodynamic analogy would be the
> distinction between "induced" drag (the price paid for "lift") and
> "parasite" drag, which are both components of the total drag.
> Sincerely, and 73s from N4GGO,

I am not an aerodynamics type, so drawing that analolgy only helps to confuse. You might as well use optics!

I know you are trying to be helpful John, but the IREE definition doesn't seem to clarify the issue.

To put some numbers on my first example, if I have an NEC model of a centre fed half wave dipole with zero conductor losses, mounted over real (ie lossy) ground, and feedpoint R at resonance is say, 60 ohms, and total power in the *far field* divided by I^2 is say, 50 ohms, is Rr 50 ohms? Is the power "radiated" from such a dipole ONLY the power that makes it to 'distant space', or is radiated power input power less dipole conductor losses?

The IREE definition suggests that I need also to state that Rr is 50 ohms at the centre, and the term is is of "limited utility" (not unambiguously clear?) because of the lossy ground reflections.

If indeed the term Radiation Resistance is only applicable in lossless scenarios as suggested by the IREE dictionary, what it a clear and unambiguous language for the real world?

Cheers
Owen

Modeling of J-poles and ground plane verticals shows considerable mutual
coupling to the feedline, and the Slim Jim almost certainly behaves the
same in this regard. The amount of common mode current this induces and
consequently the amount of pattern distortion it causes depends on the
feedline length and its path to ground. When the current is significant,
you'll probably need two current baluns (common mode chokes), one at the
feed point and the other about a quarter wavelength down, to reduce it
to a low value.

I theorize that the dependence of common mode current on feed line
length is a possible cause for the widely varying reports on how well a
J-pole radiates -- some people get lucky, some don't.

Hi Owen,

All of this neatly fits into Broadcast Band transmission where the
current pulse (we are now into the shadow zone of SWR) occurs at the
feedpoint of an antenna that is conventionally a quarter wave tall,
the current can be measured, and the far field power is known. The
matter of "lossy media" has been studied (BL&E) and that variable
reduced by good engineering practices (which brings us back to the
known far field power).

>The "reference to a specified point" suggests that if one gives a value for
>Rr, it is necessary to also state the reference point. Is that what it
>means?

The "reference" is typically the current node. It gets messier with
more complex antenna design.

>This is exactly the lack of clarity that is troubling me.

This implies the more complex designs following (or not following)
what you reject as "rules of thumb." Or at least their appearance.
I'm sure there are long and elaborate academic treatises that explain
the current node current measurement in relation to the known radiated
power. I haven't read any of them that I can glibly quote here.

>This does not address the issue of ground reflection that I mentioned.

I will return to your original and comment to that:
>>Some implications of the above are that:
>>- Rr of a horizontal half wave dipole with zero conductor loss, above
>>real ground, would have Rr less than R at the feedpoint by virtue of some
>>loss in waves reflected from real ground;

There are two mechanisms hiding in one description. The ground is lossy - period. The ground is reflective - period. These are two different issues in regard to radiation resistance. The Rr is not ground loss although the measure of Rr may be corrupted by Rground. That is a problem of separating out the variables. Others have described that. The reflection from ground may upset the measure of Rr as well, but if that does not upset the total power, and the current node can be measured, then you still have a way to quantify Rr.

>>- Rr of a half wave folded dipole of equal conductor diameters would be
>>around 300 ohms.

I thought someone else preceded this discussion with Tom's explanation. Maybe it went unread, or unrealized. So, in other words: A folded dipole/monopole is a current transformer. That transformation ratio is driven, in large part, by the ratio of the diamters of the conductors. You have acknowledged as much in your own specification of equal sized conductors. Having said that, the transformer is also transforming the Z of the load (Rr + Rground) by a square law. The usual sense of current node has been lost in a more elaborate design, but the transformation of it returns us to the usual Rr.

Things like vector mods (RF2422) have differential in/out, for instance.
Parts like the MAX2510 are similar.

It's true by the time you get to PA stage, that single ended seems to be
more common.

If I take a half wave folded dipole immersed in some environment where the ambient noise temperature is T, and attach a load directly to the feedpoint, the load power will be maximum when it is about 300 ohms rather than about 75 ohms, and the noise power density due to ambient noise would be K*T*300 W/Hz rather than K*T*75 W/Hz. If Rr is the (virtual) resistance due to coupling of the antenna with distant space, then surely this example suggests that Rr is 300 rather than 75 ohms.

(If I performed the same experiment with a plain half wave dipole, the load power will be maximum when it is about 75 ohms, and the noise power density due to ambient noise would be K*T*75 W/Hz.)

To some extent, my question comes to is Rr at a 'defined' point, and is that point the interface between non-radiating feed line and the radiating structure.

Yes, you could argue as Richard states that a folded dipole includes an integral transformer, but then, the generalised outcome of that argument is that all antennas are impedance transformers, Rr could be some agreed fixed quantity located at a great distance in space, or even more confusing, an non-shared arbitrary value, and that key to it all is some new concept of the antenna impedance transformation ratio.

The notion that Rr is defined at a virtual point that is between any deemed integral impedance transformation and the rest of the radiator, rather than defined at the physical feedline / radiator interface doesn't seem too sensible.

Owen

Radiation resistance is pretty much what the writer wants it to be. Consequently, it has to be explicitly each time it's used whenever an ambiguity might arise. It's simply a resistance whose "dissipation" (absorbed power) is the amount radiated. Most writers would probably argue that power lost from the near field to nearby lossy objects such as ground never got radiated, and therefore the corresponding resistance should be considered loss rather than radiation resistance. The presence of nearby ground, however, can also change the value of the remaining resistance due to mutual coupling and alteration of the current distribution, so a particular antenna doesn't have a single inherent value of radiation resistance independent of environment.

As for the location where radiation resistance is defined, I believe it's common in AM broadcasting, for example, to refer the radiation resistance of a monopole to a current loop (maximum). If this is a different location than the feed point, the resistance (neglecting loss) at the base will be different from the loop radiation resistance. The ratio of base radiation resistance to loop radiation resistance will in fact equal the square of the ratio of loop current to base current. So radiation resistance measured at the base can be "referred" to the loop by scaling by this ratio. (The power "dissipated" by radiation resistance referred to a loop or any other point has to equal the "dissipation" of the radiation resistance seen at the base or any other point. So Rr has to differ to keep I^2 * Rr constant as Rr is referred to points having different values of I.) The radiation resistance can be referred to any point on the antenna, so the writer has to specify what point is used. But one point is as acceptable as another. It's vital, though, when using radiation resistance, that the current at the defined point is used for calculations. And loss resistance must also be referred to the same point if efficiency calculations are to be made.

Some authors, for example Kraus, consistently refer the radiation resistance to the feed point. But Kraus doesn't explicitly apply the term "radiation resistance" to a folded dipole. There's nothing at all wrong, however, with declaring the radiation resistance of a folded dipole to be ~300 ohms. The power radiated is the current measured at the feed point, squared, times that resistance. It's equally legitimate to declare the radiation resistance of a folded dipole to be that of an unfolded equivalent, or ~75 ohms. If you do, though, you also have to work with the current of the unfolded dipole to make the power come out correct.

A common mistake when dealing with folded unipoles, made by at least several prominent people who should have known better (and marketing people who probably do know better but find it advantageous to be incorrect), is to refer the radiation resistance to the feed point but the loss resistance to the unfolded equivalent. This results in an erroneous efficiency calculation that incorrectly attributes an improvement due to folding. As I said, you can refer the radiation resistance to either, but if you want to calculate efficiency, you have to refer the loss resistance to the same point and having undergone the same transformation. And when you do, you find that folding fails to produce the often-claimed efficiency improvement.

Thanks Roy.

I note you observe similar variation in usage as I note.

Yes, consistency in an application is more important than a common meaning of the term, but a common meaning of the term assists simpler communication.

Regarding say, a base fed folded monopole and efficiency calculations, if the connection to ground is though of as having some actual value Rg, since the current flowing in Rg is twice the feedpoint current, consistent development of the circuit model will reveal the correct efficiency as:

Rr/(Rr+2Rg)

where Rr is the sum of power in the far field divided by feed point current squared. You don't need to fudge Rr to get the result, proper allowance of the power due to the actual current in Rg provides the correct result.

Kraus (Annennas for All Applications) effectively defines Rr as part of his development of the concept of a pair of conductors transitioning from a non-radiating transmission line to an antenna to free space radiation.

He does say "... the radiation resistance Rr, may be thought of as a "virtual" resistance that does not exist physically but is a quantity coupling the antenna to distant regions of space via a "virtual" transmission line."

It is his use of "distant regions of space" that suggests in the case of ground reflection, it is the remaining total power in distant free space after lossy reflection that is used to calculate Rr. The power lost in reflection would be a component of feed point R, but not Rr.

He also states a little earlier "... the antenna appears to the transmission line as a resistance, Rr, called the *radiation resistance*. It is not related to any in the antenna itself, but a resistance coupled to the from space to the antenna terminals." This seems fairly clear to me that he defines radiation resistance to be at the transmission line / antenna interface.

Both of these statements by Kraus are simple, but would seem to be capable of application to real antenna systems. I can't immediately think of exceptions (game on???).

In Kraus's language, ground reflections might reasonable be considered part of the 'antenna' since they influence its pattern and loss, and loss in the ground reflections is due to resistance "in the 'antenna' itself" and so excluded from Rr.

Is there anything in Kraus's statements that is wrong, or my interpretatiohn of them.

Owen

Sorry, that is plainly wrong. Clarity struck whilst having breakfast, the received power of a matched system should be independent of R.

Noise power density is simply K*T W/Hz. There is no R term.

The text should read...

If I take a half wave folded dipole immersed in some environment where the ambient noise temperature is T, and attach a load directly to the feedpoint, the load power (due to ambient noise) will be maximum when it is about 300 ohms rather than about 75 ohms. If Rr is the (virtual)

this example suggests that Rr is 300 rather than 75 ohms.

My apologies.

Owen

In real world terms radiation resistance is measured by the vector that overcomes radiation resistance or the conveyance of communication. This compels the measurement of that which is accelerated as it is an action and reaction type vector. If one doesn't have a measurement of the mass that is being accelerated then radiation resistance itself cannot be supplied. What happens to the accellerated mass has no connection what so ever to the accelleration vector.To find the accelerating vector one must first determine the efficiency of the apparatus used and this will vary dependent on the method used to produce the accelerating vector so that one can determine the losses. So if we cannot identify that vector which creates acceleration of charge where the charge is the measurement of radiation one must first determine what creates radiation so that the radiation unit can be measured. The bottom line is
that one must use a superconductor where only the accelerating vector comprises of the impedance
seen by the time varying current and where the
resistance of the radiating member is divorced from the equation as is coupling losses in the absence of a magnetic field.

True. But we can't force consistency of a term that's already ubiquitous in the literature with a variety of meanings. Saying it's so doesn't make it so.

Ok, here we go. Remember that efficiency is really a power ratio, not a resistance ratio. It reduces to the familiar resistance formula only when the currents in both radiation and loss resistances are the same.

Let's talk about Rg. An unfolded monopole has a single connection to ground, and we can call this resistance Rg. If Rr is the base radiation resistance, then the same current flows through Rr and Rg, so efficiency = Pr/(Pr + Pg) = Rr/(Rr + Rg) and everything's fine. But when we fold it, there are two connections to ground -- the "cold" side of the feedline and the non-feed monopole conductor. Each has half the original current. The "hot" side of the feedline carries the same current as the "cold" side so its current is half the original value also. You have your choice for Rg -- you can consider it to be the original ground system resistance but with twice the current flowing through it as through the feedpoint resistance; or you can split the original into two equal parallel resistances of twice the value, each with the same current as at the feedpoint. In the first case, you get the equation you posted. In the second, you get Rr/(Rr + Rg). We've basically referred the ground resistance to the transformed feedpoint.

The surest way to stay out of trouble is to always calculate efficiency as a ratio of powers. If you use I^2 * R for radiation power and loss power, you can't go wrong, regardless of where you choose either R to be, as long as the I is at the same point.

> Kraus (Annennas for All Applications) effectively defines Rr as part of his development of the concept of a pair of conductors transitioning from a non-radiating transmission line to an antenna to free space radiation.
>
> He does say "... the radiation resistance Rr, may be thought of as a "virtual" resistance that does not exist physically but is a quantity coupling the antenna to distant regions of space via a "virtual" transmission line."
>
> It is his use of "distant regions of space" that suggests in the case of ground reflection, it is the remaining total power in distant free space after lossy reflection that is used to calculate Rr. The power lost in reflection would be a component of feed point R, but not Rr.

Well, we can get carried away with this, too. Nearby ground sucks power from the near field and that power is never radiated. The longer distance ground reflection primarily responsible for elevation pattern development uses power which has been radiated from the antenna conductor(s). Is that reflection "distant"? When you calculate an antenna's efficiency, do you include the power radiated from the conductor before or after the ground reflection? What about power that's lost by radiation to space? It's just as surely lost for terrestrial communication as power warming the ground. Answer: It's entirely up to you. You could even consider all energy which doesn't strike your receiving antenna as "loss". All you have to do is clearly state what you're including and what you're not.

> He also states a little earlier "... the antenna appears to the transmission line as a resistance, Rr, called the *radiation resistance*. It is not related to any in the antenna itself, but a resistance coupled to the from space to the antenna terminals." This seems fairly clear to me that he defines radiation resistance to be at the transmission line / antenna interface.

Kraus is consistent with this, but other respected authors use the term radiation resistance differently. The few who use the term radiation resistance when lossy ground is present, though, seem to regard near-field coupling loss to ground as loss, and not consider far field reflection in efficiency calculations at all.

> Both of these statements by Kraus are simple, but would seem to be capable of application to real antenna systems. I can't immediately think of exceptions (game on???).

As I said above, how distant?

> In Kraus's language, ground reflections might reasonable be considered part
> of the 'antenna' since they influence its pattern and loss, and loss in the
> ground reflections is due to resistance "in the 'antenna' itself" and so
> excluded from Rr.
>
> Is there anything in Kraus's statements that is wrong, or my
> interpretatiohn of them.
>
> Owen

Kraus isn't wrong. Neither are the other respected authors who use the
term differently. I'm sorry, but you're looking for something that
doesn't exist, and I don't see the point in trying to invent a strict
definition just for your own use.

Richard
I will certainly make the installation code compliant. What I was looking for help on was how to make it effective in avoiding damage from lightning. I have read all of the applicable material from the Polyphaser, NIST, and several other sites but what I was hoping to elicit was specific guidance on what size strap to use for the down conductors and what size to use for the ground ring so that they might actually work rather than just comply with the code. I can certainly add any regular wire conductor that would keep the electrical inspectors happy since I already have 2/0 bare copper for the ground ring; were only #2 is required and, the ridiculously undersized, number ten that the code requires for down conductors in hand.

810.58 Grounding Conductors =97 Amateur Transmitting and Receiving Stations.
Grounding conductors shall comply with 810.58(A) through (C).
(A) Other Sections. All grounding conductors for amateur transmitting and receiving stations shall comply with 810.21(A) through (J).
(B) Size of Protective Grounding Conductor. The protective grounding conductor for transmitting stations shall be as large as the lead-in but not smaller than 10 AWG copper, bronze, or copper-clad steel.
(C) Size of Operating Grounding Conductor. The operating grounding conductor for transmitting stations shall not be less than 14 AWG copper or its equivalent.

810.21 Grounding Conductors =97 Receiving Stations.
Grounding conductors shall comply with 810.21(A) through (J).
(A) Material. The grounding conductor shall be of copper, aluminum, copper-clad steel, bronze, or similar corrosion-resistant material. Aluminum or copper-clad aluminum grounding conductors shall not be used where in direct contact with masonry or the earth or where subject to corrosive conditions. Where used outside, aluminum or copper-clad aluminum shall not be installed within 450 mm (18 in.) of the earth.
(B) Insulation. Insulation on grounding conductors shall not be required.

(C) Supports. The grounding conductors shall be securely fastened in place and shall be permitted to be directly attached to the surface wired over without the use of insulating supports.
Exception: Where proper support cannot be provided, the size of the grounding conductors shall be increased proportionately.
(D) Mechanical Protection. The grounding conductor shall be protected where exposed to physical damage, or the size of the grounding conductors shall be increased proportionately to compensate for the lack of protection. Where the grounding conductor is run in a metal raceway, both ends of the raceway shall be bonded to the grounding conductor or to the same terminal or electrode to which the grounding conductor is connected.
If metal enclosures such as steel conduit are used to enclose the grounding conductor, bonding must be provided at both ends to ensure an adequate low-impedance current path.
(E) Run in Straight Line. The grounding conductor for an antenna mast or antenna discharge unit shall be run in as straight a line as practicable from the mast or discharge unit to the grounding electrode.
(F) Electrode. The grounding conductor shall be connected as follows:
(1) To the nearest accessible location on the following:
a. The building or structure grounding electrode system as covered in 250.50
b. The grounded interior metal water piping systems, within 1.52 m (5 ft) from its point of entrance to the building, as covered in 250.52
See the commentary following 250.52(A)(1).
c. The power service accessible means external to the building, as covered in 250.94
d. The metallic power service raceway
e. The service equipment enclosure, or
f. The grounding electrode conductor or the grounding electrode conductor metal enclosures; or
(2) If the building or structure served has no grounding means, as described in 810.21(F)(1), to any one of the individual electrodes described in 250.52; or
(3) If the building or structure served has no grounding means, as described in 810.21(F)(1) or (F)(2), to an effectively grounded metal structure or to any of the individual electrodes described in 250.52.
(G) Inside or Outside Building. The grounding conductor shall be permitted to be run either inside or outside the building.
(H) Size. The grounding conductor shall not be smaller than 10 AWG copper, 8 AWG aluminum, or 17 AWG copper-clad steel or bronze.
(I) Common Ground. A single grounding conductor shall be permitted for both protective and operating purposes.
(J) Bonding of Electrodes. A bonding jumper not smaller than 6 AWG copper or equivalent shall be connected between the radio and television equipment grounding electrode and the power grounding electrode system at the building or structure served where separate electrodes are used.

Owen
Believe it or not the NEC only calls for number ten American Wire Gage (AWG) or 5.261 (mm)2 for protective grounding conductors. Bonding conductors between electrodes are only required to be number six AWG or 13.30 (mm)2. So leaving aside the bad joke that is the NEC requirements I'm trying to get some idea of what best practice might be.

John
Would you mind sharing what you base that advise on? Much of it
appears contrary to NIST guidance on protective grounding and current
industry practice.

Owen
It is relevant as a consensus standard but it is not adopted as local
or State law.  Do you have a link to a copy that can be read online?

Bruce
I don't know were your getting the idea that I'm confusing the purpose
of the grounding when I specifically asked about lightning protective
down conductors. The other places that I have seen copper strap
grounds is on the Polyphaser web site. Polyphaser is one of the most
respected names in lightning protection for radio installations in the
United States. Let me be clear that since I'm using balanced antennas
I have no pressing need for an RF ground. Lightning grounding is what
I'm interested in and I'm looking for someone with actual field
experience of best practice.

Owen
The NEC only requires 5.261 (mm)2 for the protective down conductor
and 13.30 (mm)2 for the bonding conductor between electrodes. Since
those sizes are at best a bad joke I was hoping to elicit best
practice advise on what size the conductors should actually be as well
as advise on how to accomplish the bonding of the interior single
point grounding buss bar to the exterior grounding conductors and
Grounding Electrode System.

Ok, well the question is whether you give it importance, or stay with NEC.
I think it turns out that you have a copy, read it and make you own mind
up.

If it was me, I wouldn't waste the money on an inadequate protection
scheme.

Owen

I only did it once but the j-pole design papers often call for the
feedline to be coiled tightly -- a few turns -- just below the feed
point. I have made and used several of these "choke baluns" for HF
because failure to use a balun seems to screw up my VSWR readings.
Does this strictly apply to 2m j-poles, too? I don't know.

I have used 7 turns on 1 inch PVC about an inch below the feedpoint on
the Arrow style J Poles I have built.  I see no significant change in
the SWR when coupling my hand to the feedline over the first 2 meters
below the feedpoint on the 2 meter band.  Per my version of "significant".

For best results, follow Roy's advice.

This borders on regret - for what, I haven't a clue.

> I can certainly
>add any regular wire conductor that would keep the electrical
>inspectors happy since I already have 2/0 bare copper for the ground
>ring; were only #2 is required and, the ridiculously undersized,
>number ten that the code requires for down conductors in hand.

This is not a beauty contest for the diversion of inspectors.

Forgive my not continuing to quote you further as I see that it

NOWHERE employs strap in its description of conductors.

Here is a clue. Call up your insurance agent that provides coverage for your house against lightning strike. Ask him if your policy would be honored if your home did not conform to code. Ask him how many claims had been made for lightning damage to homes that did conform to code.

#6 is a minimum required by code here in the Midland MI area. As it's a minimum, I would not use anything less than #2 Copper.
>
> More than 8 feet of ground rod is of little consequence.
>
That depends on your soil conditions. Here I'd probably agree as the soil is usually quite moist and just a couple feet down is just plain wet.

However a string of ground rods tied together can be quite effective.

>All ground rods should be tied together. Don't put your house between
>two electrodes!

I'd put a circle of them around the house, all tied together every 16', but due to the garage and driveway, that is not possible.
>
>The ground rods are better directly under the structure that they are
>protecting.

I have a 100' 45G 10' from the NW corner of the garage. Tied into it is a grounding system consisting of 32 or 33 8' ground rods connected together with over 600 feet of bare #2.

This system consists of a ground rod about a foot outside the concrete bare in like with each tower leg. The cable is clamped to each tower leg and comes off in a curve to the ground rod and is extended out in a straight line at least 80' with additional ground rods every 16' (give or take a tad) This system also ties into the house electrical ground. There is an additional run that goes directly from the ground rod at the base of the 45G to the 25G on the West end of the shop. From there it goes on around the shop to the mast holding the 144/440 vertical and around the south side to enter the shop to provide grounding for the station and computers. This also ties the shop ground (which is on a different electrical feed) to the house ground.

>
>The system does not absorb massive high energy strikes. It starts
>bleeding off the energy before the strike builds and thus minmiizes
>the effect.

Mine has taken at least 17 direct hits that have been visually verified. All that energy had to go some where.

The bleeding off theory has been pretty well discussed and discarded on the tower talk reflector. Read up on the Polyphaser site. They have some good information. Those lightning balls or porcupines have proven ineffective. The major work for lightning rods and ground systems is to divert the lightning away from the interior of buildings and process control systems in Industry.

Read the new NEC code for tower and antenna grounding. There is a reason I went with #2.

I agree with the #2 recommendation. OTOH there is nothing that will
protect an installation from the big atypical Positive lightning, or
super strikes. That's the stuff that blows holes in airplanes.

The Polyphaser site has a tutorial on grounding tower legs and coax
shields. this would be applicable to connecting to the 1" pipe.
Use lots on NoAlox between the strap and pipe.

73

>

Lossy media is that which absorbs radiation passing through it. IOW it heats up. This is different than say the outside air being warmed through conduction from the earth's surface being in turn heated up by radiation from the sun.

> The "reference to a specified point" suggests that if one gives a value for Rr, it is necessary to also state the reference point. Is that what it means?

Hello, and yes, you would have to specify where the quantity applies. Rr is being calculated as I^2 * Rr = Power radiated. The usual reference point is the feedpoint of the antenna. Note that the antenna feedpoint could also be defined to include matching networks and even transmission line. Of course if these other components also radiate they contribute to the antenna's radiated power.

>
> This is exactly the lack of clarity that is troubling me.

>
> This does not address the issue of ground reflection that I mentioned.
>

It doesn't matter to the definition of Rr what other agencies may modify
an antenna's characteristics. For example, we measure (at a particular
frequency) the real (resistive) part of its feedpoint impedance. A
portion of that resistance is due to ohmic losses in the earth, antenna
structure, and any other items forward of the feedpoint. The remainder
of the resistance is Rr. In this example the "antenna" consists of the
monopole and its near-field operating environment.

Well, I've spent a great deal my professional career as an EE dealing
with USN shipboard antennas and just happen to have ham radio as an
"office" related hobby. As I said in my previous post I don't have a
problem with what Rr means. It seems like a rather straightforward and
simple concept. I think you're trying to read more into it then is there.

> To put some numbers on my first example, if I have an NEC model of a centre
> fed half wave dipole with zero conductor losses, mounted over real (ie

> the power "radiated" from such a dipole ONLY the power that makes it to
> 'distant space', or is radiated power input power less dipole conductor
> losses?
>

The radiated (far field) power is what is relevant to Rr. The radiated
power is the power accepted by the antenna designated feedpoint less the
other ohmic (items that are dissipating heat) losses forward of the
antenna feed and in its (near field) vicinity. Also, by "accepted"
power I mean the actual power into the antenna terminals (incident power
less reflected power).

> The IREE definition suggests that I need also to state that Rr is 50 ohms
> at the centre, and the term is is of "limited utility" (not unambiguously

No it doesn't.

> If indeed the term Radiation Resistance is only applicable in lossless
> scenarios as suggested by the IREE dictionary, what it a clear and
> unambiguous language for the real world?
>
> Cheers
> Owen

The definition doesn't say that (cf the word "limited"). Again I think
you're trying to read items, that while possibility contributing to the
measured/calculated Rr value are irrelevant to the basic definition.
IOW those other items such as earth grounds if present really ARE part
of the antenna. The power radiated by the antenna could propagate as
ground wave, sky wave or in combination - it doesn't matter. Sincerely,
and 73s from N4GGO,

Parts come from the code books,
some from experience and
some from observation.

The #6 wire is out of the code book. Reason and observation leads to the conclusion that whatever you use there is the possibility of a lightning strike that can vaporize it. That also supports the notion that the charge must be bled off over time (seconds?) rather than shunted to ground instantaneously. In a moment of lapsed judgment I installed a ground rod for an invisible dog fence on the opposite side of the house from the electric service ground. I also allowed the TV-Internet cable ground a few feet away. Lightning strikes carbonize cable coax connectors. Dog fence controller factory repair is $40 per event. After much consideration I ran a #6 wire between the power service ground and the rods for the dog fence and cable ground rods. Much thought was given to this because that route involved putting a conductive path along the floor joists just beneath my bed! I considered the fact that copper plumbing is routinely routed without concern wherever it is needed. No more service calls to the cable company, no more repairs needed for the dog fence controller!

I have concluded that if more than 8 foot ground rods were required for effect or code, the supply houses would be selling them. I cannot argue with redundancy though. THERE IS A POTENTIAL PROBLEM WITH GROUND RODS THAT ARE NOT BONDED WITH AT LEAST #6 WIRE! Common sense dictates that protective system be continuously bled to a common level rather than allowed to build up a differential charge.

My observations have led me to the notion that the frail little #6 wire does not provide the path for a direct strike. It only suggest a route for the strike. A straight direct route is more likely to be followed to ground than a longer twisted route. Lightning is a "boss force". It can and will ionize its own path in a seemingly whimsical manner. A spin-off cable loop has been popular for antenna entry points for many years. This is one of those considerations that may not do anything but it cannot hurt either!

Whatever you do it must:
Meet code, follow the law
Satisfy the Insurance company, don't give them room to wiggle out of a claim!
Enhance safety
Protect your property.

In spite of all the precautions and preparations that you take you can only reduce your exposure to the natural forces in life! My dog Shadow (a black Labrador Retriever) endorses this by retreating to the Master Bathroom during storm conditions. Midnight, (Shadows Cat) concurs by hiding in the basement workshop under those same conditions. I disconnect all ham radio antennas.

At this time I seem to have my problems at bay... but I also have professionally installed lightning rods on the house.

Roger, I like your response better than mine.

It sounds to me like you have the ultimate solution. I arrived at my
operating point one step at a time and I quit working on the problem
when I quit having problems!

I have a non-Ham friend that lives a couple of miles down the ridge
from me that continues to have lightning related problems that may
benefit from your advice. I will pass along the Wisdom.

Thank you!
John Ferrell W8CCW

A few (2 - 4) ferrite beads, the sort used on the glass computer monitor video lead, works very well slipped over the co-ax just below the bottom of the J. Best of all you can get them for free...

I've seen a couple of postings so far recommending a single balun at the feedpoint. While this takes care of conducted common mode current, it doesn't eliminate current induced on the feedline from mutual coupling. All the single balun does is to insure that the current is near zero at the single point where the balun is inserted. Current is still induced on the feedline, and you end up with a current maximum a quarter wavelength down the line -- the distribution looks just like it does on an antenna (which the feedline has actually become), with the balun location being the end of the "antenna". The balun can even make the induced current worse if the effective common mode open circuit at the balun insertion point results in a more nearly resonant feedline length. The only way to really effectively reduce the induced current to a low level is to break up the resonance of the feedline by inserting a second balun about a quarter wavelength below the feedpoint as I recommended earlier.

Roy Lewallen, W7EL

I know. You appreciate my free lectures.

Now is time for the solitons: http://en.wikipedia.org/wiki/Soliton

Real waves are not simetrical. They are the chain of solitons. Radio waves also.

I'm a bit late to the party, but...

To me that seems like a lot of elements on a short boom, (I use 7L on
a 29' boom) but properly adjusted they can give more band width rather
than gain as gain is more a function of boom length. Also, how do they
get 50 ohms at the feed point of a dipole driven element in a 6L
Yagi?

Direct connect can work, but how well is another question. It may
give a good match, it may transfer the power efficiently, but again
the question is, how well does it work.

Jim Brown's (K9YC), A Ham's Guide to RFI, Ferrites, Baluns, and Audio
Interfacing ...
www.audiosystemsgroup.com/RFI-Ham.pdf is well worth reading. when it
comes to using toroids and the old "coil of coax" as a rather
inefficient current balun (which I used for years).

I worked a station down in Central America (on six) who had his new
rig on the bench testing it with a short piece of wire stuck in the
coax connector...I'm in Michigan. He could have said, that short piece
of wire on the bench was a good antenna...at that moment.

But given you get a good match, the pattern is still going to be
distorted. You can take 4 2.4" OD toroid cores with 4 or 5 turns of
coax through them to make a very good current balun (bout 5,000 ohms
isolation) and center feed a split driven element, then the antenna
is not really "direct connect" as the "matching device" is between the
feed line and antenna even though it can be the end 5 to 8' of coax
wound on the cores.

BTW, run the coax through the toroids before installing the connector

>
>
>I wonder how far above the A4 the 6 meter needs to be. I only have a
>5ft mast.

Should be and what you can get away with are often quite different. A friend has a bunch of antennas on one tower that are all way closer than they *should* be, but he gets acceptable performance, at least to him and that's all that counts. Having said that, 5' would be considered very close and 10' would be much better. OTOH you will probably be satisfied with the performance over a simple antenna.
All antennas are a series of compromises as are installations. IOW we use what we have and hope for the best. You only have a 5' mast, so I assume that a taller mast is out of the question which makes "how far apart do they need to be" a moot question. Then the real question is: Will they work with only 5' of spacing? The answer is ... Probably and they probably will work fairly well.

One element to keep in mind (no pun intended) is with the antennas only 5' apart they may tend to detune one or both a bit and also lower the feed point impedance. But it's what you have and you won't know until you try.

Getting things to work is half the fun, at least it is to me...as long as getting the project to work does not run into frustration. <:-))

73 & Good Luck.

The model I was working with was at 14 mhz with the feed point at
about four feet.

Re:
http://www.nytimes.com/2010/07/13/technology/13apple.html?hpw

"Consumer Reports, America�s trusted source of product reviews, said
it would not recommend the iPhone 4 because of a hardware flaw with
its antenna that sometimes resulted in dropped calls.

"... its antenna, which is built into a steel band that encases the
phone.

"After users reported problems with signal strength and dropped calls
when they touched the lower-left portion of the phone, however, Apple
suggested that consumers hold the phone differently or use one of many
bumpers to insulate the antenna. It also said that all phones suffered
from similar problems when they were cradled a certain way.

"These comments were widely laughed at in gadget blogs. "

Just thought I would submit this to the Laughing Academy.

73's

I can't tell from your comments if you think there is a problem with the
phone or Consumer Reports.

From what I've heard there are repeatable problems, but I've heard no
coherent explanation of what might be occurring.

The thing that seems to be consistent is that left handed users have
more reported problems than right handed users.

Hi Tom,

By any account, there's a problem. Now, as the iPhone has had demonstrable connection issues in the past, it was blamed on AT&T who bore the brunt of that criticism.

Reports long following this past connection problem has borne out that AT&T had adequate 3G capacity, and AT&T chose to take the bullet for their customer (Apple, if anyone has lost track) who had a marginal design in their protocol stack (poor through-put and high retry traffic).

> From what I've heard there are repeatable problems, but I've heard no
>coherent explanation of what might be occurring.

The NYT article's symptomology bears out across many reports from a variety of sources.

>The thing that seems to be consistent is that left handed users have
>more reported problems than right handed users.

That would be apocryphal, at best.

The short answer is that fashion trumps technology. The rising trend of using the iPhone as an eReader flies in the face of what was formerly a nebbish activity. Fashion forced the turnaround, not the technology (I've been reading books on my Palm Pilot for 6 years - I have not suddenly become an �ber-hip literary savant overnight by virtue of that trend as anyone here will quickly testify.)

The only thing that remains a mystery, for me if for no one else here, is the literal specification of the antenna. Google (gasp) fails me.

And that does seem to be the crux of the matter. What is the antenna?
And what does it interact with that's not, be it part of the phone or
part of the user?

Can anyone make a recommendation, based on actual training and experience, as to what width and thickness of copper strap would be needed as the down conductor from the antenna mounts at the peak of my house roof, some twenty five feet above local terrain. I have a a mount for an antenna at one gable end and a mount for a weather station sensor array at the other. What thickness and width should I use in the earth between the two Grounding Electrode Systems. I will drive five eighths inch copper rods, each eight feet long as far out from the foundation as I can get them or eight feet were possible. On one end that will be only six feet due to the proximity of the property line. At all of the other rod locations I will be able to keep them at least eight feet from any underground obstructions. To compensate for the proximity to the foundation wall to the first rod I will use rod couplers and drive it to hard rock or sixteen feet whichever comes first. I'm guessing that in keeping the remaining rods at least eight feet out from the foundation and sixteen feet apart that I will only have four rods total in a ring around the back side of the house. What is the best way to attach the copper strap to the support masts and eve brackets themselves? Do you know of anything that will make a good connection to the one inch galvanized iron pipes that I'm using for support masts?

Can you recommend a technique for bonding the interior grounding buss at the operating position to the exterior vertical copper strap. I have no idea how that is usually done.

Hi Tom,

The antenna is reported as being the metal trim that surrounds the
perimeter of the phone. As that is much too large for the frequencies
involved to be taken literally, there is more to the story that
remains clouded. Maybe I'm wrong....

If the loop (or dipole) is suitably matched, it doesn't give much
polarization diversity. Perhaps no phone does anyway.

Insofar as being "part of the user," we well know the EM of HTs and the hand/body contribution. If such were the case, then this would be an agnostic problem that users of all mobile phones would complain of (which mildly refutes what the gadget blogs dismissed). On the other hand, the �ber-hip, whose complaints are more vocal for their "pain," would be outraged at the notion of their simply enjoying the identical experience of techno-trash. Amazing what a 10 fold cost differential brings to your perception of quality of service.

Hi Tom,

Consult the NEC code for your area. I have never seen them specify strap in any situation, and don't try your own interpretations of what "continuous"or "direct" means.

In this part of the world, we have an Australian / New Zealand Standard (our version if you like of ANSI, BS etc) which explains the rationale behind lightning protection, a method of estimating the downcurrent for protection design purposes and a process for designing down conductors.

Broadly, the scheme is that downconductors are designed to withstand a few donwstrokes in quick succession without melting the down conductor. If you work from a peak current of 20kA, it would lead to a down conductor in copper of at least 25mm^2 which is about #2 to you folk.

I regularly see hams recommend much thinner down conductors, and can only assume that there is not regulatory guidance or requirement, and I wonder at the effectiveness of using #6 as often recommended, especially aluminium as is often the case. Note that reducing conductor size is a double whammy, you increase the resistance (so the power), and decrease the mass that has to be heated to melting point, and so the energy required.

But, firstly, you should determine if there are regulatory requirements, such as NEC etc.

The question of equipotential bonding conductors ought be dealt with in the same way, though that is not to imply that they will be the same size.

Owen

I don't remember the sources but I have concluded that the Grounding wire should be no smaller than #6.

More than 8 feet of ground rod is of little consequence.

All ground rods should be tied together. Don't put your house between two electrodes!

The ground rods are better directly under the structure that they are protecting.

The system does not absorb massive high energy strikes. It starts bleeding off the energy before the strike builds and thus minmiizes the effect.

Home improvement stores sell #6 wire, ground rods and connectors.

If you are going to get crazy with a grounding system, ground rods
should be spaced their length. 3 rods can be placed to form an
equilateral triangle. Other geometric arrangements that build on the
triangle pattern are good. An example would be a hexagon representing
6 triangles with a rod at each node. Cant think of the name of the
company right now but they make a lot of lightning suppression and
grounding equipment and have free downloadable info. Im sure googling
lightning arrestor will get it for you.

Exactly! May often see during an electrical disturbance little spikes
off the top point of a lightning rod doing its job.

I've been through many 'lightning events' in my day with the closest
direct strike to a neighbor's tree. Also a former wife in my old house
that was hit after she and new husband had cut all the leads to my
ground rods from high TV antennas.

A drawing of the iPhone 4 I saw recently (I think it was in a recent SJ Mercury News) indicates that there is a deliberate gap in the metal rim of the iPhone 4 - the rim that serves as the antenna. This gap is located near the lower left corner of the phone.

If I understand correctly, the iPhone 4 has a tendency to drop calls if it's held in a way which allows the user's hand to bridge across this gap... presumably "short-circuiting" the antenna in some way.
A left-handed grip on the phone would put the user's palm right across the gap - this may be the worst-case situation.

Applying an insulation of some sort to the area of this gap (an iPhone case, or duct tape), or holding it in a way which doesn't cause the hand to bridge the gap, reduces or eliminates the problem.

It sounds as if this iPhone has some sort of dipole or loop antenna design, which requires that a high RF impedance be maintained at this point. The low RF impedance of human skin is apparently enough to de-tune or load the antenna in some way which disrupts its function.

Has anyone run across a web site showing a "tear-down" of the iPhone 4, which might clarify its antenna design?

There are a number of issues here, that are Mutually Exclusive, but added together cause the iPhone4 to seem to have some problems.

Issue One. Apple has already admitted that the Signal Level algorithm, used in the IPhone4 was seriously flawed in how it displayed Signal Level. (Bars) When the Phone displayed 4 or 5 Bars, it may actually only be receiving at a 1-2 Bar Level. This they have corrected with a Software Patch.

Issue Two. The Multi-Band Antenna design in the iPhone4 is a Kludge Compromise at best, and burying it in the Metal Frame where Left Hand users put the flesh against it, seriously detunes it. Apple is in the process of hiring a small group of Engineers, with expertise in this area.

The combination of these two issues seems to cause, what appears to be a High Signal Level, to drop to "No Bars" when some users grasp the iPhone4 in a particular way. The "Simple Fix" is don't hold it that way. The more complex "Fix" is to redesign the Cellular Antenna, and move it to the Top of the iPhone4. This would require that the BlueTooth/Wifi antenna be redesigned as well. Apple is looking to do that in the 2nd Generation iPhone4.

Just remember that Apple isn't particularly adept in the RF Arena, and

the iPhone/iTouch/iPad are their only small products that have RF
Antennas, this small. Also remember that some of their Laptops, of past
years, had some serious Wifi Antenna placement problems, and remember
that Wifi at that time was only a Single Band, not a Three Band System,
like the iPhone4.

Just saying.

If it is applicable, it seems that for a Class 1 structure (less than 75'
in height???), the requirement for the main down conductor is 57,400
circular mils CSA if copper, that is about 29mm^2 or #2 conductor.

By contrast, #6 is 26,000 circular mils, has approximately twice the resistance per unit length, half the mass per unit length, and somewhere just less than 25% of the stroke current withstand of #2.

Owen

You seem to be confusing Lightning Ground, Electrical Ground, and RF Ground, here, and they are basically three different things. If you build a Lightning Ground, it may, or may not, be an effective Electrical Ground. Neither of these will be of any use as an RF Ground, unless you happen to live in a Salt Marsh. You see Copper Strap Grounds, mostly on Wood, or Plastic Boats, (ships) used to extend the RF Ground, from the SeaWater, to the Radio, or Antenna Tuner. Here the Strap becomes part of the Antenna System, and they need to be engineered, so as to provide as low of impedance connection, between the two as possible, over the widest Frequency Range. Some work better than others. Some don't work at all, and the only way the radio functions at all, is because of Good Band Conditions.

I must replace the 100+ ft. coax run in a receive-only antenna system that includes a Transi-Tap transient discharger and a Magnetic Longwire Balun impedance transformer, and both have SO-239's.

It used to be RG-58, but foam-dielectric 75-ohm sat-TV coax is everywhere, low-loss, well shielded, cheap etc.and I am sure I can live with the extra mismatch.

However, its shield is aluminum foil. It can't be soldered, so the plug has to be twist-on or maybe crimp-on type. The center conductor is copper or copperclad and therefore can be soldered.

Years ago I did use things that looked like screw-on PL-259's on the 300+ ft. sat-TV coax run that feeds my homemade T2FD. They work perfectly, but I'd be darned if I can find some anymore around here. So I have to buy online unseen, if I can find any. I located exactly one expensive supplier, in the UK, that lists "twist-on PL-259's for RG-58" and they don't look like mine.

QUESTIONS:

- Do twist-on / crimp-on PL259's for RG-58 still exist?
- Do they go by any special name I can't guess?
- Whatever they're actually called, do they fit sat-TV coax?
- Suggestions for suppliers? Or should they be available everywhere?

I hope I hadn't chanced on a nonstandard type!

Thank you in advance!

N1JPR/I2

I think you're right.  "Design Flaw" Someone messed up testing big time.

Aren't cell stations vertically polarised.  The one near me is, and one
of the IF's is smack on 144.005 Mhz.

From a casual look at the phone the metal band seems to be a continuous loop. Its unlikely that there is a physical coupling between it and the RX/TX, so any tuner or coupling is going to be affected by the hand grasping it. Since suggestions have been made to hold the phone in a different place, I would guess that the coupling method is suseptible to adsorbtion effects and that the hot parts are near the base of the phone.

FWIW Every mobile phone I've played with has the antenna and coupling circuitry near the top behind the display.

We had a long discussion about this about a month ago.

The short of it is to buy the appropriate COMPRESSION connectors (not crimp on or screw on) ones and use adaptors.

You have to make sure you get the right ones, the ones for RG-59, RG-6 and RG-6QS are different. F connectors are easy to find and cheap, BNC ones are harder to find and more expensive.

Geoff.

Not any more.. recent phones (last several years) put the antenna at the
bottom to reduce the SAR number, since the top of the phone is next to
your head, and the bottom isn't. There's a really good explanation from
a guy who does, oddly, wireless device antenna design consulting..

Hi Bruce,

Jim's second link (which I quoted in my response to him) gives very
specific signal levels. Aside from that, and as is obvious by the

numbers, the "bars" are merely window (with apologies to M$) dressing in any phone (except as a RF exposure risk indicator).

>Issue Two. The Multi-Band Antenna design in the iPhone4 is a Kludge

A bumper would seem to mitigate the risk. Conformal coating would to some lesser extent. All-in-all, the amount of metal seems to be consistent with best engineering practices (but, perhaps, not best consumer packaging practices).

My new antenna can easily handle this job.
You make it for the lowest frequency and it will handle all the
frequencies above at a constant impedance..... and with more gain and
the radiater smaller in size!

No!
Total resistance =3D R1+ R2 The trick is to reduce
R2 in value so more current is being applied to radiation. Very simple
my dear Watson.

The rumor I heard was that they tried to put in a "better" antenna to
cure problems with dropouts. While it does have more gain it is
sensitive to the way it's held. Basically they traded one problem for
another.
Any confirmation or rebutal would be appreciated

Jimmie

My new antenna can easily handle this job.
You make it for the lowest frequency and it will handle all the
frequencies above at a constant impedance..... and with more gain and
the radiater smaller in size!
****
-
Sounds great. Where can we see the construction details?

Waiting on patent issueance. I have put details out before but in general hams believe every thing is known and then fire insults. Frankly, history shows a lot of fraud in antenna new design such that hams have given up on improvement so I am not to quick on providing details up front any more.

Jim.  Thanks for the above links.  The Youtube vid was most interesting.
I certainly wasn't aware of the gaps in the metal banding nor of the SAR
requirements.

Yep ! Totally drowns out any signals.  A waste of time complaining.
Leakage signals are within spec, according to them.
Anyway I've now given up trying and taken the antenna array down.
To be honest its been some time since I was last active.

There's a whole raft of issues..

One is that cellphones aren't analog FM anymore, so they suffer from the "digital cliff" problem.. If the Eb/No is good enough that the FEC works, then it works great, but a dB or so worse, and it doesn't work at all.

This is so different from most people's practical experience with communications that it is disconcerting. E.g. if you walk away from me while talking, your voice gets fainter and the SNR gradually drops, but it's not like you've walked out of the "cone of silence" where it goes from fully intelligible to not at all intelligible in milliseconds.

And, the fact that this happens on a packet by packet basis means that at the threshold, it "stutters", which is also non-intuitive and non-physical.

And then, the cellphone companies have managed to convince us that really crummy sound is ok, even at the full bit rate of <8kpbs. The voice codecs are impressive, but face it, it still doesn't sound like 56kbps u-law or 25 kHz NBFM, what used to be called "toll-quality"

```

i hope this is more interesting than your pick-up-sticks patent, i
still get a good laugh at that one when i read it... amazing what bull
the patent off will pass through.

And then there's the PSTN ala 2010. We have been discovering a lot of new things about that that we suspect even the carriers haven't noticed, or at least appreciated. And it's all started showing up in the last year. Like average LD call completion failure has been 4% for 10 years. Yup it's actually that high. Except this year it's 6%. And possibly still climbing. Can't tell you the test conditions (NDA needed), but it's millions of calls per year.

One of the first odd things we noticed was the occasional location code 3 from the supposed destination. That one is now obvious, but the first time you see it it's very perplexing.

And more things are showing up, mostly disturbing if you expect the PSTN to remain the relatively predictable thing that it's been during the SS7/TDM/ISDN era. So much is changing we are making a new training program for our analysts on how to recognize what's now going on versus what used to go on.

Richard has learn me that the dipoles are polarized not waves.
Monopoles do not need the directional orientation.

Directional patterns are the result of interference.

Is is trouble with understanding that the all scientists work on plasma?
Only students are in the solid aether. But they simply do not know that the
famous equations describes such.
Vectors describes the motions of something. Students should not be told what
it is. Because the goal is math (field method) teaching.

Hi Richard, good day:

Again you give me another rethoric answer... Please, tell us how to
measure to distinguish Osc. A from Osc. B, having Osc. A 4*10^28
quanta and Osc. B 4*10^28 +1 quanta, having each 80 m quantum 2.3 *
10^-19 J.

Your answers are making me remember =3D> "It was the only explicit
answer you will ever get" or "Superman's cataracts with his xray
vision. This is probably going to be your only direct
answer." (Please do not go upsetting, I am joking).

You dislike my examples, you dislike R & H & K classic and obviously
really good peer reviewed book reference (and examples), you dislike
university notes, you dislike analogies, you dislike Sagan... Today I
know all things you dislike, what I do not know is how measure A and B
oscillator to distinguish each other... :>D
Remember, you are rebutting things stated in standard university
physics book, does not reverse the burden of proof.
Please be a good boy, be plain and do not resort to old tricks such as
posting esoteric rocket science hiper-specialized incomprehensible
answers :>)

The problem I had was the use of "energy flow balance" which implied
equal energy flow into and out of any point at any time. Your more

detailed description explicitly includes stored and dissipated energy, which as we've both said, makes it possible for energy flow into and out of a point to be unequal at times, while obeying conservation of energy by being equal on the average (when dissipated energy is accounted for as removed from the system). The more detailed detailed description should help alleviate misunderstandings some readers might have had.

I can't recall ever having come across that term, but then I'm not a physicist.

SRI, I ommited to say the example of the University of New Mexico link
it is similar to the one given in "Physics for scientists and
engineers" (Serway & Beichner, my copy is in spanish). They say the
same about it.

Humoroues note: Richard Feynman do not share your dislike for
analogies he compare corks in water with charged objects fields :>)

its too hot for this, i'm going for a swim... maybe some nice
longitudinal waves in the water will make me feel better.

Excellent. Some agreement.

> this
> case is very misleading if you try to extend it to cover other cases.
> in general it takes infinitely long and you must account for the
> infinite series of reflections. =A0

Of course. But this illustrates one of the benefits of "appropriately
selecting" examples. One can choose examples that do not take forever
to settle and therefore can be analyzed in finite time.

> that is why the approximations

To which approximations do you refer?

> used
> to come up with the sinusoidal steady state solution is so useful, and
> exactly why it can not be applied to steps and square waves and other

Are you suggesting that it is inappropriate to use the reflection
coefficient computed at an impedance discontinuity to predict the
behaviour of a transmission line excited with a 'step, square wave or
other non sinusoidal constant sources"?

> and in your infinite line example it never reaches steady state so the
> step wave propagates forever

So is this 'step wave' an EM wave, according to your definition of an
EM wave? If not, what would you call it?

Well, it was Cecil's question and I answered it in the context of the
limited information that he provided.

But I agree, we would learn much more if the experiment included some
internals of the box.

> for instance, take your infinitely long transmission line. =A0as an

> that energy propagating forever as an em wave

Yes, indeed. Though black boxes still have their uses as an aid to
learning. Or to simplify analysis when some aspect is simply not
of concern.

...Keith

Well, you are digging your hole deeper and deeper. You really should
take a pause and try to understand the significance of "Continuity
equations". Do seriously consider Kerchoff's current law as an
example.

Sorry, I posted my answer in another branch of the thread (I hope not to have bothered our friends...)

Hi Richard, good day:

Again you give me another rethoric answer... Please, tell us how to measure to distinguish Osc. A from Osc. B, having Osc. A 4*10^28 quanta and Osc. B 4*10^28 +1 quanta, having each 80 m quantum 2.3 * 10^-19 J.

Your answers are making me remember =3D> "It was the only explicit answer you will ever get" or "Superman's cataracts with his xray vision. This is probably going to be your only direct answer." (Please do not go upsetting, I am joking).

You dislike my examples, you dislike R & H & K classic and obviously really good peer reviewed book reference (and examples), you dislike university notes, you dislike analogies, you dislike Sagan... Today I know all things you dislike, what I do not know is how measure A and B
oscillator to distinguish each other... :>D
Remember, you are rebutting things stated in standard university physics book, does not reverse the burden of proof.
Please be a good boy, be plain and do not resort to old tricks such as
posting esoteric rocket science hiper-specialized incomprehensible answers :>)
.....
I ommited to say the example of the University of New Mexico link it is similar to the one given in "Physics for scientists and engineers" (Serway & Beichner, my copy is in spanish). They say the same about it.

Humorous note: Richard Feynman do not share your dislike for analogies he compare corks in water with charged objects fields :>)

So you now are in agreement that flows must balance if charge (or
energy)

is to be conserved. Excellent.

For greater certainty, I paraphrase: "Only the leading edge has an EM
wave".

What is follows just after the leading edge since it is not an EM
wave?
What is it? What do you call it?

Now back to the square wave with a two year period...

After the rising edge goes by, which I assume you will still call an
EM wave, what follows until the falling edge occurs a year later?
Is it an EM wave?

If so, how is it different than what follows the rising edge of the
step wave? They both look like DC for a year.

If not, why is it not an EM wave?

No reflections here, so little impact on any argument.

> state where EM waves cease to exist so your argument involving forward
> and reflected waves falls apart.

When, exactly, does the EM wave cease to exist?
Just after the edge passes? Or only when the edge makes it all the way
back to the source?

> power as one of the conserved quantities.

Do study Kirchoff's current law and its relation to conservation of charge.
Recall that current is charge per time.

Map this to conservation of energy...
Current is to power as charge is to energy.

The relationship and utility is the same.

Or you could do mass flow in a pipe junction; mass must be conserved.
Mass flow is to power(energy flow) as mass is to energy.

Or, pick any number of conservation laws to use as examples.

But back to Kirchoff...

I am sure you have made extensive use of Kirchoff's current law and will
find "Keith's" power law equally useful, once you understand how it works.

They are quite analogous.

...Keith

PS: Since the power law is apparently unnamed, and this is holding you back, I make the somewhat presumptuous suggestion of naming it after myself. But if you would prefer to call it Cecil's law, that would work for me, as long as it has a name and you no longer feel that it can not exist because it is unnamed.

So you finally admit I was right all along, adopt my original
position, and claim it was yours all the while. Old trick - won't
work. I studied similar equations half a century ago when I studied
the conservation of energy principle. I told you long ago that your
P(t) =3D V(t)*I(t) equation did not contain all the energy in the
system.

I have never posted anything that disagrees with the continuity
equations. You are the one who chose to ignore the delta-dot-v terms
and have reversed your original position by introducing the continuity
equation. All you had in your equation previously was the de/dt term.

Do you still believe in the conservation of instantaneous power
principle?

> So you now are in agreement that flows must balance if charge (or
> energy) is to be conserved.

No, you remain confused and mistaken. Energy flows (de/dt) do NOT have to balance. That's what I have been saying all along. Energy must balance whether it is flowing and/or not flowing. I told you weeks ago that the sum of your instantaneous energy flows do NOT include all the energy, i.e. there is no such thing as conservation of instantaneous power (energy flow). If you don't correct that basic misconception, you will never get it.

The continuity equation aids my side of the argument, not yours. It proves that you have been wrong all along when you did not include all the energy in your instantaneous power equation.

Back to the LC oscillator. At the instant when all of the energy is stored in the capacitor, energy flow has been completely destroyed, i.e. de/dt=3D0, yet there is plenty of energy in the capacitor. Your P(t)=3DV(t)*I(t) =3D0 equation completely ignores the energy in the capacitor when I(t)=3D0 and I have told you all this many times before. The continuity equation only highlights your error of ignoring the stored energy.

> After the rising edge goes by, which I assume you will still call an
> EM wave, what follows until the falling edge occurs a year later?
> Is it an EM wave?

If electrons (carriers) are not being accelerated and/or decelerated, i.e. if DC steady-state exists, then there are no EM waves.

So now you are pushing a conservation of current principle as well as
a conservation of power principle? You can *destroy* the current and
power with the flip of a switch. Can you destroy charge and energy?
Good Grief!

I detect evasion. Is there a problem providing an answer?

Is what follows the rising edge an EM wave? Or not?

I invite you to view the 15.84e-9 Hz square wave as one year at
a constant value of voltage and current followed by another year
with zero voltage and current, repeated.

Or you can perform the fourier transform and obtain an infinite
number of odd harmonics of the 15.84 nanoHz fundamental.

Does either one of these views assist you with deciding whether
there are EM waves present during the one year intervals where
the signal value does not change?

If the square wave frequency was 1 MHz, would you have the same
difficulty deciding? Why not?

...Keith

More evasion. So are now saying there may indeed be an EM wave
present with DC? Even with DC, the electrons are not moving with
constant velocity but hop from atom to atom. Seems like
acceleration and deceleration to me.

Maybe you should just start with Kirchoff's current law and understand
what it says before following my suggestion to compare it with the
conservation of energy law.

You seem to have forgotten what you almost certainly once knew.

Google will provide many adequate explanations.

Not EM but the electric wave.
```

In the free electron laser (halbach array) is DC and waves are produced.

If the electron beam is periodically deflected the current is DC but the all works like the dipole.

You do not read my posts.

In the free electron laser the DC steady-state exists and there are electric
waves.

longitudinal waves in the water will make me feel better.

Next time look at water waves with the Stokes eyes:
http://en.wikipedia.org/wiki/Stokes_drift

They are more longitudinal than transversal. They transport the mass and the
energy.

If you are in the UK in October, you may be interested in coming along to the RSGB 2010 Convention:
http://www.rsgb.org/rsgbconvention/index.php

The full program for the convention is here:
http://www.rsgb.org/rsgbconvention/events_programme.php

On the Sunday morning (10 October) I will be giving a couple of presentations on the AIM4170. The first will cover the basics of antenna measurement and the 4170, and the second will illustrate the use of the 4170 as a design tool.

Live demonstrations of the 4170 will be the main feature of the presentations, and will include tuning a 4m groundplane, trap tuning, designing a 160/80m trap dipole, measuring quartz crystal parameters, using the Smith chart, quarter-wave stub tuning and measuring the impedance at the antenna feedpoint. The final demonstration will show how to control the analyzer remotely via a WiFi link, allowing you to tune your antenna while standing in the yard (or on the roof or at the top of the tower).

The presentations will be based on the material at :
http://homepage.ntlworld.com/wadei/aim4170.htm

The venue for the Convention is Horwood House in the county of Buckinghamshire:
http://www.rsgb.org/news/article.php?id=0027

Horwood House is located about 50 miles (80km) north-west of London, close to the city of Milton Keynes.

A further local attraction, just 5 miles (8km) from Horwood House, is Bletchley Park, home of the World War II Codes and Ciphers School where the Enigma and other encryption systems were broken:
http://en.wikipedia.org/wiki/Bletchley_Park

If you plan to come along to my presentations at the Convention, please let me know and I will reserve a front seat for you!

On Jul 6, 12:20=A0am, Keith Dysart <keith.dys...@gmail.com> wrote:
> Is there a problem providing an answer?

I don't know how to measure the exact answer. How many photons does it take to cause a measurable EM field at one cycle per two years? If the EM field is too low to measure, how do you know it is there at all? Blind faith in a math model?

> Does either one of these views assist you with deciding whether
> there are EM waves present during the one year intervals where
> the signal value does not change?

No they don't. The problem is random/natural/man-made EM noise. When the EM wave level drops far below the EM noise, how can you measure the EM wave level? If you cannot measure it, you are back to angels on the head of a pin.

> If the square wave frequency was 1 MHz, would you have the same
> difficulty deciding? Why not?

Because I could measure those EM waves.

> So are now saying there may indeed be an EM wave

> present with DC? Even with DC, the electrons are not moving with
> constant velocity but hop from atom to atom. Seems like
> acceleration and deceleration to me.

No, EM waves do not exist at DC steady-state. Those are free electrons which do not change orbital levels. The only force acting on an electron during DC steady-state is a constant force.

> Maybe you should just start with Kirchoff's current law and
> understand what it says before following my suggestion to
> compare it with the conservation of energy law.

You have two phasor currents flowing into a junction. One current is one amp at zero degrees. The other is one amp at 180 degrees. What is the total current flowing out of the junction? Hint: There is no such thing as a conservation of current principle. If the quantity can be completely destroyed to zero at any time, it cannot be conserved.

> You seem to have forgotten what you almost certainly once
> knew.

And you seem to have invented an impossible metaphysics. So do you really know how many angels can dance on the head of a pin?

I'm afraid "periodically deflected" violates the definition of steady-state.

I>'m afraid "periodically deflected" violates the definition of steady-state.

In AC coulombs/s in one direction is not const In the DC is.
In this sense in the free electronn laser is DC.

I gave you that solution: multiply them. Very simple exercise available to anyone with sufficient bench equipment. Skip the quotes of undergraduate scribblers with little imagination that shrug their shoulders at their own failure.

>Humorous note: Richard Feynman do not share your dislike for
>analogies he compare corks in water with charged objects fields :>)

Feynman was a humorous fellow, but you are using undergrad texts instead of his - why?

As I've already offered, drop all the frills and adornment and tell me what scale the source of your 80M problem exists at:
1. Subatomic,
2. Atomic,
3. Molecular.

Hello Richard, good day.

Thank you very much for your friendly company, I enjoyed this
conversation but I think it is time to go back because it is leaning
dangerously close to an eristic exercise :>)
I am sure we will have very interesting other things to talk about our
common topic.

Best regards

Your friend Miguel

correct, the 'step wave' is not AN EM wave, it is an infinite
summation of EM waves.

do you not think that it is telling that there is a current law and a
voltage law, but not a basic power law included in basic circuit
theory? maybe there is a reason for that.

DC does not an EM wave make... nor does one year make DC, the
summation is infinite, you must wait FOREVER for DC to be achieved and
by then you just won't care any more.

beware cecil... remember, there are electric fields, and there are
magnetic fields, there is NOT an Electro-Magnetic 'Field'!  there are
Electro-Magnetic WAVES but NOT a 'Field'!  he is trying to draw you
in!  remember DC is forever, any direct current creates a Magnetic
FIELD... and any net charge imbalance would create an Electric FIELD
(though DC does not require a charge imbalance, only a moving charge
at a constant velocity).  But in any case if it is a stream of charged
particles moving at constant velocity forever they create an Electric
FIELD... BUT there is no Electro-Magnetic WAVE produced by those
static fields.

note, if you google 'electromagnetic field' you will indeed find may
misuses of the term, including wikipedia that inappropriately
abreviates it EMF, which we all know means Electro-Motive Force.  The
term 'electromagnetic fields', little f, and plural, is commonly used
to refer to collections of electric and magnetic fields.  This is seen
quite often when talking about relativistic transformations where the
electric and magnetic fields are linked by the frame transformation.

Excellent attempt at diversion.

> If the
> EM field is too low to measure, how do you know it is there at all?

Plenty of joules are being moved per second. There is no reason to
expect the field to be small.

> Blind faith in a math model?

The signal is well above the noise.

What if the signal was a sinusoid instead of square wave?

Is it then 'obviously' an EM wave?

> > If the square wave frequency was 1 MHz, would you have the same

> > difficulty deciding? Why not?
>
> Because I could measure those EM waves.

Same joules per second. Lots of energy to detect. My 'diversion'
detector is still firing.

I suppose that is an obtuse hint that you understand Kirchoff's
current law, but why not just come out and say it.

Assuming that you have grasped it, study how it is derived from
and relates to the 'conservation of charge' law. Remember that
current is the rate of flow of charge.

Then contrast those two laws with the previously discussed
power (rate of flow of energy) and 'conservation of energy'
law.

You should be able to discern the similarities.

Well at least there is no attempt at diversion here.

What is the shape of these EM waves of which there is an infinite number which sum to a step?

...Keith

But previously you said the line would settle after one round trip if
the source was matched. How is this consistent with having to wait
forever?

Hello friends:
```

A few years ago I posted in this newsgroup a doubt from a friend of me about DC current (such a batery connected to a lamp) radiating EM waves... It was in topic "Antenna gain question" (2005-10-31). My answer wold be that classic physics postulate EM radiation from accelerated charges in closed circuit because charges are under centripetal acceleration (I though of ciclotron radiation analogy, of course). My friend Richard Clarke disagreed with my hypothesis and I archived the issue for a couple of years, (he give me some analogies with moving cars, I remember...)

Time later I was casually reading some pages from Kraus and I found the answer! :>D: Kraus says: "a charge moving at uniform velocity along a curved or bent wire it is accelerated and radiates".
The clue was in words "straight wire" , he says: "Electric charge moving with uniform velocity along a straight wire does not radiate".
then, a DC also must be rectlinear (perhaps it must move on a geodesic, but I do not know general relativity enough to say it) (*)

(*) "Antennas" John D. Krauss - Second Edition -1997 Page 50.

Of course, the similarities are so obvious I don't even need to state
them. Why are they not obvious to you?

There is a principle of conservation of energy. There is no principle
of conservation of energy flow (power). All you have to do to destroy
power is stop the flow of energy. All you have to do to create power
is to start the flow of energy.

There is a principle of conservation of charge. There is no principle
of conservation of charge flow (current). All you have to do to
destroy current is stop the flow of charges. All you have to do to
create current is to start the flow of charges.

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

 radio/personal-intro

```
 Subject: Guide to the rec.radio Newsgroups

Good. You have made some progress then...

> create current is to start the flow of charges.

and partially contrasted the two. But you did not show how Kirchoff's
current law derives from conservation of charge.

Still, you have made some progress, so I will try again with showing
the derivation, though this time with charge and current.

Conservation of charge requires that:
  the charge added to a region
  - the charge removed from a region
  equals
  the charge originally in the region
```

+ the increase of charge stored in the region

When the charge can be described with functions of time, we can write:

Qin(t) - Qout(t) =3D Qoriginal + Qstored(t)

Differentiating we obtain

Qin(t)/dt - Qout(t)/dt =3D 0 + Qstored(t)/dt

At a junction, where charge can not be stored, this reduces to

Qin(t)/dt - Qout(t)/dt =3D 0

Alternatively

Qin(t)/dt =3D Qout(t)/dt

Recognizing that Q(t)/dt is charge flow per unit time or current
we obtain Kirchoff's current law, colloquially: the current flowing
in to a junction equals the current flowing out of a junction.

I leave it to you to do the similar derivation for energy, based
on conservation of energy. The result will be

EnergyIn(t)/dt =3D EnergyOut(t)/dt

And similar to Kirchoff, this applies at a juncion, a place where
energy can not be stored.

Of course Energy(t)/dt is just a mathematical expression of energy
flow or power, so we obtain

PowerIn(t) =3D PowerOut(t)   (at a junction)

But don't beleive me. Do the derivation yourself. You can pattern
your derivation on the one above for Kirchoff.

I'd go on to show how my analysis of your circuit carefully
picked junctions that could not store energy, but I have found
it better to educate one step at a time. So we can do that
later.

...Keith

T'is when the thing you claim not to know has nothing to do with the problem at hand.

As i pointed out, the energy levels are well above the noise.

And you skipped the intriguing question...

If the signal was a 50 W sinusoid at 15 nHz, would you have the same reluctance to declare it an EM wave? It is a sinusoid. What criteria could it possibly fail to satisfy?

At what frequency would you no longer be reluctanct?
1 microHz
1 mHz
0.1 Hz
1 Hz
10 Hz
100 Hz

1 kHz
10 kHz
?

Real applications run at 10 kHz so I assume you would accept,
without concern, at least this number. Where would your
trepidation begin?

How do you define energy of a node without reference to another node.
How is it measured?

Sorry, your examples are irrelevant to the technical fact that there
is no conservation of current principle because charge can be stored.
Until you can prove a conservation of current principle, you are
wasting my time.

If the ratio of the conductors stay the same, there should not be a change
except the losses go up. As you streach the coax, the shield and the center
conductor will get smaller. Also the dialectric will have to get smaller.
If they do not srink at the same ratio, the impedance will change depending
on which conductor gets smaller the fastest.

The losses will go up because the center conductor and the outer conductor
are smaller. This is the simple IR loss of the conductors. It is the same
as going from a rg-8 to a rg-58 type coax.

I'd be pleased to trade two buckets of prop wash for a coax stretcher.
Any takers?

Walt-

Contact Tucker Electronics to see if they are willing to deal!

One such device is the General Radio 874LK20L line stretcher.  Tucker
may have them in stock. See
<http://www.tucker.com/java/jsp/product_partno874LK20L_invid17338_condR.h
tm>.

The product is described in a GR document at
```

<http://www.tucker.com/images/images_spec/00001006.pdf>. It is supposed
to have a constant impedance.

Hi,

I tried a shortwave radio group first, but no answers.
Should have posted here, first.

Enjoy sw listening, but frankly not all that sharp re antennas.

Over the past few months, I have seen several ads for those handheld sw
receivers and transceivers. From different mfgs.
About the size of the typical hand-held scanner receiver.

They all seem to cover up to at least 30 MHz, and most beyond.

Got to thinking about this a bit.
What do they use for an antenna for 30 MHz and below ?

I have a long end fed antenna for my listening.
Obviously they have a short "something" antenna.

How effective is a short "something" around 5 to 10 MHz, e.g. ?

How can it work down there at all ?

I can visualize s tuned ferrite loop, such as the very old fashioned AM
table radios used to have, but wouldn't this only be effective over a
very small range ?

Or, do they expect you to hook up something "decent" to it, even though
it is supposed to be portable, and is very small ?

Any technical explanation on this would be most appreciated.

Thanks,
Bob

Hi Bob,

A make and model number would get you a more definitive answer. However, for the broader question, and as you undoubtedly expect, more antenna is better - to a point. Some will argue, theoretically, otherwise. I go with results.

When I was in South Africa (no, not the World Cup), I took along one of Radio Shack's cheapest SW radios. It had the conventional whip, and it offered the conventional whimp. However, having foresight, I also took along about 20 feet of wirewrap wire with a quarter taped onto one end. At the close of day, I would wrap one end around the shortened whip and I would toss the quarter into the rafters (we stayed in thatched covered huts), all of a ten or fourteen foot height; and signals came booming in from all over the continent and Europe.

Another thing missing from these small jobs are a tuned front end. In fact, you can spend a lot of money on SW radios and still not get front end tuning. A preselector, or simple antenna tuner (as cheap as one as you can find, or build one for $10) will go far, far, far.

I seriously doubt if there is any shortage of copper for coax or any
other type feed line.  It's probably more a matter of someone
forgetting to order stock, or enough stock.  Or, like gasoline, it's a
contrived 'shortage'.

As for a 'coax stretcher', all is not lost, I have one.  No, I do not
loan it out.  I might be talked into selling it, but you probably
couldn't afford it, sorry.

Hi, hi, I do not quite understand/translate your jokes: do you dislike
Resnick's "granularity"? I think it is a sort of energy acne :>)

You said you could hear an insect shooting your window then I asked
you if you can hear sound 80 dB below insect shooting your window. 80

dB example it is only a about difference (quotient) of magnitudes. Or you do not read well or I not write well my sentences -the last has a probability of 0,99- :>)

Certainly, my book is in spanish, the original is "Physics" Vol II, Extended version, 4th ed. ISBN 0-471-54804-9 (I do not have it), read from here. Yes, it is dated 1992 a little old, doesn't it?. so... can we today measure quantum acne from large scale 3,5 MHz oscillator at room temperature? (Use caution to answer me because your words can turn against us and someone may be tempted to postulate "The uncerntainty VSWR principle" and rots all here :>D)

Yes, yes, I by far prefer Xerox button to my own non senses :=3DD :=3DD. (another sting to my friend Cecil?).

Well, I stop here because I think our friends are going to reprimand me for not posting serious matters.

Thank you very much for your friendly and patient with me posts .
Miguel LU6ETJ.

Hi Miguel,

Good joke. Others may not be aware that Buenos Aires is one among cities that have the highest psychiatrist to population ratio in the world. To set the record straight, Seattle has a very high suicide rate. This in no way intimates that you are crazy and I am about to off myself (this may disappoint some that drawl).

>You said you could hear an insect shooting your window then I asked
>you if you can hear sound 80 dB below insect shooting your window.

You presented the analogue of car vs mosquito. You expressed the magnitude of difference. I disputed neither, accepted them, showed that the difference(s) could be perceived. Why add a new variable? If you are not, are you challenging your own analogue?

> 80
>dB example it is only a about difference (quotient) of magnitudes. Or
>you do not read well or I not write well my sentences -the last has a
>probability of 0,99- :>)

You are now extending it to 160dB of difference.

As I said, you either have your magnitudes inverted, or are now mixing metaphors. The argument is in failure mode. This is invariably the fate of metaphor/analog/allegory when it is forced to replace simple math for observable and demonstrable science.

To touch on allegory, the snake in Eden (read Texas) introduced analogues (read Hallelujah - let there be Photons!) and seduced (read perverted) logic to obtain mastery over creation (read RRAA).

Don't blame the guy with the horn. :-)

>Certainly, my book is in spanish, the original is "Physics" Vol II,

Not too many of us get new copies from the future, so I am not particularly upset about its copyright date.

>so... can
>we today measure quantum acne from large scale 3,5 MHz oscillator at
>room temperature?

Did you miss my comments about noise floor? Can you breath,

unassisted, under water? Does a tree make a noise when it topples on
the Moon? Can you feel the tingle of 110VAC when you are being struck
by lightning? Do these questions sound like Cecileo? (As I have long
ago blocked his postings, I assume our newsgroup victim has at least
once made an allusion to his torment by the inquisition.)

There are 10,000 ways to fail and you found at least one that was
documented. I showed you an equal number of success (1) and that is
unsatisfactory. Could it be answered that between the two examples
that one exhibits a huge S+N/N? In other words, why at:
>room temperature?
Do you have a New York flight to catch to solve the Financial crisis?
Plan on the next flight out tomorrow and cool the room down.

>(Use caution to answer me because your words can
>turn against us and someone may be tempted to postulate "The
>uncerntainty VSWR principle" and rots all here :>D)

"However your VSWR may vary, no Standing Waves were interfered with in
the making of this response."

Hi hi, Why I find it more hard to translate your writings than another
guys ones? is it a peculiarity of your playing with words or your zone
manners? I am sorry because I miss some of your subtleties or
grammatical tricks and I suspect they have more funny meanings that I
can capture :>)

I believe what we have more here are psychoanalysts not psychiatrists
(I read something about it time ago), but do not worry I am a little
crazy too! :>)

Look, my first idea example was compare difference in marbels size
with hydrogen atom size (about 10^8) to point to granularity, but
inmediately I realized that dealing with differences in size was not a
correct example and turn to Ec example. You said our retinas sometimes
can perceive individual light photons, no? then I pointed to an eigty
meters photon had 10^-8 smaller energy than green photon.

I was telling we are talking about truly classics system therefore quantum effects (photon) it is useless because in our level of discussion oscillators/transmitters do not manifest quantum effects because its very high quantum numbers Of course I know (do I know?, really?, mmm) correspondence principle.

Why at room temperature? Do we see if I understood your question... at room temperature because we Hams usually make our TL Bird Truline measurements at room temperatures. Answer this your question? (my freezer do not go beyond -20 Celcius degrees!). Theorical/extreme cases are welcomed too but... to rebut normal/standard situations?
I do not believe you has blocking Cecil posts, no no, you say it =3D> we have a lot of psychoanalysts here: one of them are whispering to my ear just now, you really like him, remember TV series: "The odd couple"? :>D
.....
(You see?, I'm lost with some interesting sentences such "However your VSWR may vary, no Standing Waves were interfered with in the making of this response." If tomorrow I find my london friend I ask his helping to translate better your entire post :>)   )

73, and now being 23:31 I will take my girlfriend LU2ET to a night trip motorcycle by the city. Well... 2ET has been my XYL for over thirty years :>)
Have you a really nice motorcycle as Cecil? eh?

Bob-

Like Richard, I have one of the small Radio Shack SW Receivers. I think it was made for them by Sangean. It has a telescoping antenna that may be as long as 36 inches when extended. No, a 36 inch antenna is not as good as a longer wire for Shortwave reception.

Someone with a better understanding of antenna theory may be able to calculate just how much worse it is, but suppose it receives a signal at a 20 dB lower level (1/100th the power level or 1/10th the voltage) than a full-size antenna. All you need is a stronger signal to make up for it. But when propagation is good, signals can be quite strong.

Even so, it wouldn't hurt to take along some extra antenna wire!

Fred

>Hi hi, Why I find it more hard to translate your writings than another guys ones? is it a peculiarity of your playing with words or your zone manners? I am sorry because I miss some of your subtleties or grammatical tricks and I suspect they have more funny meanings that I can capture :>)

Hi Miguel,

Sorry for the loss in translation. It is what is called "deep metaphors" that go beyond the simpler ones of mosquitoes against the windshield.

>I believe what we have more here are psychoanalysts not psychiatrists (I read something about it time ago), but do not worry I am a little crazy too! :>)

You are correct (about analysts...).

Here, the game of language is found in the ellipsis (or the parenthetical aside - this one being doubly self-referential).

>Look, my first idea example was compare difference in marbels size with hydrogen atom size (about 10^8) to point to granularity, but inmediately I realized that dealing with differences in size was not a correct example and turn to Ec example. You said our retinas sometimes can perceive individual light photons, no?

Yes, in the best of circumstances half of those that impact the retina. This returns us to background noise and S+N/N.

> then I pointed to an eigty meters photon had 10^-8 smaller energy than green photon.

Hence the eight orders of scale comparison. Yes.

>I was telling we are talking about truly classics system therefore quantum effects (photon) it is useless because in our level of discussion oscillators/transmitters do not manifest quantum effects because its very high quantum numbers Of course I know (do I know?, really?, mmm) correspondence principle.

You can experience one photon, however could you state that it was not two instead? I have designed with components that are specifically photon counters. These are called photomultiplier tubes (PMTs for short). Where they do not match up against the eye for dynamic range, spectral bandwidth, or quantum efficiency; they do present us with individual events within a group. Our eyes do not count very well.

>Why at room temperature? Do we see if I understood your question... at
>room temperature because we Hams usually make our TL Bird Truline
>measurements at room temperatures. Answer this your question? (my
>freezer do not go beyond -20 Celcius degrees!).

So, I am to understand that you want to measure quantum effects at energy background levels in excess of 0.04 eV or roughly 10 TeraHertz. I don't think you can afford the Bird plug for that band.

I come from a field called Metrology. This is so rare that many, many engineers have never heard of it. It is the science of measurement. If you want a quantum correlative to frequency, this field abounds in them. The Atomic Clock (Cesium Beam Standard) comes close, but the Josephson Junction is a direct translation of frequency to voltage. It is also an instrument in quantum computing.

I will offer a page for your consideration:
http://www.ptb.de/en/org/2/Inhalte/Josephson/_josephs.htm

Anticipating your objection that the frequencies involved are not in the 80M band; I would offer that is satisfied easily through frequency multiplication. (The Atomic Clock does this in reverse and no one complains about that.)

Anticipating your objection that this is not done at room temperature; true, the junction is cooled far below what is available to you - but is this about your limited resources, or is it about being done? Don't join the legions pleading destitution (poverty) as that might migrate into the metaphors and analogies for a very poor (sorry for the pun) outcome.

>Theorical/extreme
>cases are welcomed too but... to rebut normal/standard situations?

>have a lot of psychoanalysts here: one of them are whispering to my
>ear just now, you really like him, remember TV series: "The odd
>couple"? :>D

Yes, I do block him. There are traces that sift through the cracks, but that doesn't elevate them to poignancy. Again (do I have to repeat this?), this is about S+N/N.

"The Odd Couple" is a good cultural reference. I would suggest (and I hope you have access to) "House." Cecil is among those who cannot be trusted to write on the white board.

If you don't have TV access to this series, try an episode from:
http://www.hulu.com/search?query=house&st=0
You write and understand English quite well, but if listening to it is not easy, I am sure that watching 10 minutes around that white board will give you enough "body language" to translate the psychology

easily.

>.....
>(You see?, I'm lost with some interesting sentences such "However your VSWR may vary, no Standing Waves were interfered with in the making of this response." If tomorrow I find my london friend I ask his helping to translate better your entire post :>)   )

This might be lost on your English friend too, because it constructed with cultural references (it is suppose to be bad form to have to explain a joke - but here we go):

"However your VSWR may vary"

is a variant on YMMV that you may see as shorthand. It means Your Mileage May Vary. It is a reference to how car gas performance was reported by those who sold cars. They would quote government tests that were generally optimistic, and the real experience would disappoint customers who saw poorer results. The customers would complain to the vendor. Thus the vendor would qualify with "the government reports this car gets 50MPG on the Highway - but your mileage may vary." Thus the usage of YMMV is a cultural joke indicating disappointment was likely.

" no Standing Waves were interfered with
in the making of this response."

is a variant on the disclosure you see at the end of movies:

"No animal was harmed during the filming of this movie."

You will, no doubt, draw out the meaning of Standing Waves, interference, and response as being related to soothing those people who cry uncontrollably when they see the movie "Bambi." We have a similar class of sob-sisters (your English friend should be able to translate that).

There was a long discussion here about using compression type F connectors
(and BNC) with RG/6QS coax recently. I suggest that you look it up and refer
your friend to it.

The general consesus was that RG6QS was a pretty good choice for amateur
use. Not the best, but for the usual low power setup, it was ok.

There is RG6QS coax designed for satellite downleads (1-2gHz) so if you
get that it should work for 900 and 1296mHz, possibly 2.4gHz.

It is very important to note that we were talking about COMPRESSION
connectors, which compress from front to back sealing the cable in,
and NOT crimp on connectors, which are squeezed from side to side and often
fall off.

Geoff.

Usually known on the business as 'Snap and Seal' (or 'Snap-N-Seal',

'SNS' etc) connectors. This type is now the only type used in most of
the UK cable TV industry (and, no doubt, in the USA). They are very
difficult to pull off, and are essentially watertight.

For example:
http://www.wittenberg-antennen.de/snapnseal.pdf
<http://www.3starinc.com/lrc_sns11as_snap_n_seal_rg-11_cable_f_connector.
html>

You do, of course, need the appropriate tool.

>and NOT crimp on connectors, which are squeezed from side to side and often

>
'Proper' crimp connectors, properly crimped, with the 'proper' tool, are
also hard to pull off - at least, mine are!

Ian Jackson wrote:
> You do, of course, need the appropriate tool.

They are relatively cheap. I've seen a set of tool, cutter and stripper
(3 tools) and 20 F connectors for as little as $12 on eBay. Here, a month
ago I paid $60 for such a set without connectors, today when I went to
the same store, the tool alone was $30. Last month they did not have the
tool alone.

The bad news is that they raised the price on the connectors from $.90 each
to $1.25 each, but dropped them to $.77 if you bought 100. They had 2 packages
of 50 and to convince me not clean them out, they gave me the 100 price
for 50.

>>and NOT crimp on connectors, which are squeezed from side to side and often

>>
> 'Proper' crimp connectors, properly crimped, with the 'proper' tool, are
> also hard to pull off - at least, mine are!

From my experience, the tools are more expensive, and the skill level required
is much higher to get the done properly. Most of the crimp on ones are not
water resistant, while most of the compression ones are.

Geoff.

That reminds me of the medical profession two hundred years ago when
doctors believed that there was no such thing as a virus because they
couldn't see it and besides that, how could it possibly exist and be
alive without a cellular structure?

Don't worry about it, Miguel. I am an English major and understand
your English better than Richard's. He is not unlike a court jester
who talks in riddles and takes pride in himself when nobody
understands.

Actually, human rods can detect one photon but that small impulse does not reach the brain. It takes about nine photons for our brains to experience photons. It's a transmission line problem, not a detector problem.

Hi all

I'm looking for software that will work with my Rigexpert AA-200 Antenna Analyzer. I'm using the Antscope software that came with it. I was wondering if there was any other software out there that would work with it. Any ideas?

Thanks

Thanks for the reply. My friend has been a ham for over 40 years and was an electronic engineer involving RF. I have been a ham close to 40 years and also know a bit about the types of coax. He just does not want to use the rg-6 types. As we both have many ot the connectors for rg-8 and adaptors for the 8x and 58 types it is no use to get the rg-6./ Also as pointed out you often need special connectors or tools to install the F connectors for outside use. He has a small setup of just two or 3 antennas and does not want to buy special tools for the rg-6. I have often use over 1000 watts for the low bands and also work weak signals on 6 meters and above. That leaves me out for the smaller coax also.   Neither of us like the solid small wires for outside use on 80 meter dipoles. Too much flexing in the wind.   I am not sure what the losses would be for the copper coated steel often used in some of the rg-6 at frequencies below 10 mhz where he wants to use it.

It just seems that some things seem to be in short supply at differant times in this country.   Around 1974 there was a gas shortage (I think that was when the shortages started), one year it was a toilet paper shortage, one year it was a chicken shortage. For about the last year or two it was an ammunition shortage for guns.

Every time it snows in the South US there is a big run on bread and milk and that runs out .

We were just wondering if the one big supplier close by was the only one having trouble getting coax.

 I don't know much about the making of coax amd other wire, but assume it is like where I work. We make polyester material that is shipped out for car

tires and other things. The machines are set up for one type of material
and ran for a while . When the warehouse is stocked with that, we change
the machines to run another type. If the inventory is running low on one
type, it may be a while before we switch over to run it again.

Maybe the quantities of coax being manufactured these days is being
affected by the increasing demand for optical fibre?

Could be. While I would think it would take a differnat plant to make the
OF, maybe not as much coax is used and some plants have shut down making the
coax.   Hard telling how many miles of coax was made for cable TV/internet

and computer connections that are now going to the OF.

Yes. Because I am interested in the antennas and Richard is an expert in it.
 In electromagnetics Maxwell and Heaveside are the experts. Available on
line.

unfortunately you have to learn modern em to know what writings of
maxwell and heaveside to bother believing... they both went through
learning periods before they came to the final transverse wave
formulations.  if you read their earlier works you will be mislead
because they were still learning and following dead end paths like
aether theory and fluid analogies.

I think you are misunderstanding, possibly because I am not expressing
as clearly as could be. I find it difficult to pick a vocabulary that
will not be confusing due to prior associations with the words. But
then words like 'entity' are too fuzzy.

The system I have in mind has ports through which energy can flow in
or out of the system and components inside the system which can
store energy. For such a system, the energy flowing in to ports
of the system minus the energy flowing out of ports must
equal the increase in energy being stored in the system.

This must be true at all times, or energy is being created or
destroyed; a bit of a no-no.

This system can be subdivided in to sub-systems for which this
energy flow balance must also hold.

As such, if the energy stored in one of the entities (e.g.
capacitor) is increasing, either net energy is flowing in to
the ports of the system, or the energy stored in some other
entity in the system is decreasing (or both). But the sum
of all the flows entering or leaving the ports, plus
the flows between the internal entities must balance on
a moment by moment basis.

Of course the expressions written to describe this will
be dependent on the details of the system. One must also
not forget to account for energy that leaves the system
as heat courtesy resistors. These can be thought of as
ports which only remove energy from the system.

The requirement for moment-by-moment balance is more stringent
than the requirement for average balance. The former inevitably
leads to the latter, but the converse is not true.

From Wikipedia, I have just learned that the concept I am attempting
to describe is known as a "Continuity equation".

What was my argument that fell apart? I am not the one pushing the notion of forward and reflected EM waves. That's you. I am just trying to help you fit square waves in to your model.

So how do you characterize a slow square wave? Say one that is 0V for one year, then 10V for a year, then 0, then...

With several meters of open circuited transmission line, what do you think is happening on the line for the year while you are waiting for the signal to drop back to zero volts? Does it have a constant voltage? And 0 current for most of that year? Is it an EM wave?

You need to read more carefully. I have never claimed they are the same.

A question for your model...

With an infinitely long transmission line excited by a step function, is there an EM wave propagating down the line?

If not, what is it that is propagating down the line? Especially at the leading edge?

The same question for you...

With an infinitely long transmission line excited by a step function,
is there an EM wave propagating down the line?

If not, what is it that is propagating down the line? Especially at
the leading edge?

> essentially the dc case IS unique in that you must wait forever for it

You have used similar phrases before. Are you suggesting that an
open circuited transmission line excited with a step function takes
infinitely long to read steady state?

Hello all, friends.

Sorry, I thought we was basically alone in this issue with Richard :>)

Then, perhaps some of you can help me if I am not capable to make my poor english writings intelligible enough. I feel as if Richard had not pointed in the direction I point. I think that because his references to S+N/N and others made me think Richard are thinking in detect low frequency wave quanta at little energy levels, and I am talking about to perceive the little LF quanta at high energy levels (large scale oscillators).
In my original example I said we are not able distinguish (today... tomorrow who knows?) Osc. A from Osc. B, having Osc. A 4*10^28 quanta and Osc. B 4*10^28 +1 quanta, having each 80 m quantum 2.3 * 10^-19 J.

(I know my friend Richard inevitably is going to penalize me for this "analogy", but it is so beautiful that I could not resist..!) =3D> The problem is such as distinguish between two zeppelins of about 1500 m^3 each one having zeppelin A only one molecule more than zeppelin B...! Do not we need an alien Roswell Grey technology for that? :>)

Last night I found in the web the "strange word", it is not "granularity" it is =3D> "graininess", graininess translate to spanish properly to "granularidad" and granularidad to english as granularity :>)

At the end of this link: http://panda.unm.edu/Courses/Finley/P262/ThermalRa=
d/ThermalRad.html
there are a similar text in its original english words =3D>

"Therefore, we see that the quantization of energy simply does not show up for large-scale oscillators. The smallness of Planck's constant makes the graininess in the energy much too fine to detect in those experiments. This is quite similar to the statement that we do not ordinarily observe the fact that the air in the room is actually made up of many, many individual molecules. Nonetheless, we can indeed perform experiments in which this graininess is noticeable, and even important. Obviously the behavior of the spectral radiancy at very short wavelengths is one such case. The phenomena involved with the photoelectric effect, and the Compton effect, are others."

I apologize for my insistence dear Richard, I do not want to be stubborn but I remember Carl Sagan telling: "Extraordinary claims require extraordinary evidence" and my posting about the very large quantum number of the 3.5 MHz Xmtrs play here the "conservative" role :>)

73 to all Miguel - LU6ETJ

PS: Szczepan: Thanks for your info.
Richard: Why a "white board"? has a special meaning? - You are saying Cecil it is as Dr. House? - Really nice car your RX-7, I envy you! - My London friend is "missing2 I owe you some answers :>(

One example you should be familiar with is Kirchoffs Current Law;
it tells you that sum of the FLOWs must equal 0 based on the
Conservation of Charge law. Recall that current is charge per
unit time.

For a more general treatment look up 'Continuity equation' in
Wikidedia where you will find "A continuity equation in physics is a
differential equation that describes the transport of some kind of
conserved quantity. Since mass, energy, momentum, electric charge
and other natural quantities are conserved, a vast variety of
physics may be described with continuity equations.".

Welcome to a new tool for analysis.

See above, though it seems the common term is Continuity equation.

Inside the box are some elements whose stored energy is increasing
at the same rate.

Expand your thinking a bit. Energy is being stored in the capacitor.
You do need to account for this. It is just another flow to track.

See above.

...Keith

Under the assumption that even though my topic involves an LNB, and
that's not technically a radio, I'll beg your pardon for pressing on
under the guise of "radio" astronomy. Maybe someone here talks LNBs and
satellite signal devices.

I constructed the battery pack in the link above, but w/o the coil. I
plugged it into the 1004ifd and immediately got something of a single
note  noise from the device. This seems wrong. Any ideas? I did not
connect to the LNB and disk.

>unfortunately you have to learn modern em to know what writings of maxwell and heaveside to bother believing... they both went through learning periods before they came to the final transverse wave formulations. if you read their earlier works you will be mislead because they were still learning and following dead end paths like aether theory and fluid analogies.

Maxwell's aether was as perfect solid with the molecular vortices. The magnetic field was the sum of the molecular.
The Faraday effect was explained. Transverse waves possible. But in solid possible are also the longitudinal.
Which of them are in reality decide experiments.

Heaviside modified Maxwell' model. His aether is also motionless but withot the molecular vortices:
http://en.wikisource.org/wiki/Electromagnetic_effects_of_a_moving_charge

Now inside the solenoid no rotations. What rotate the polarisation plane?

Heaviside (father of Maxwell' equations) did not understand Maxwell and did not agree with the rest:

"Prof. Thomson, who otherwise confirms my results, has also extended the matter by supposing that the medium itself is set in motion, as well as the electrification. This is somewhat beyond me. I do not yet know certainly

that the ether can move, or its laws of motion if it can. Fresnel thought
the earth could move through the ether without disturbing it; Stokes, that
it carried the ether along with it, by giving irrotational motion to it."

" I must, however, disagree with Prof. Thomson's assumption that the motion
must be irrotational. It would appear, by the above, that this limitation is
unnecessary."

I simply agree with Maxwell, Stokes, Thompson and the rest famous scientists
that no rotational vibrations (transverse waves).

You prefer Heaviside (engineer) and Authors of the textbooks .

Hi Miguel,

Sagan never impressed me, and this quote even less. It relies on mystical explanations when ordinary works quite well.

>and my posting about the very large
>quantum number of the 3.5 MHz Xmtrs play here the "conservative"
>role :>)

The link leads to a lot of tedious and pedantic writing.

Your new analogy fails as quickly as the rest, so by extension I must presume that the work revealed at your link fails too. That is the usual fate of tying two things together when one is a rhetorical anchor.

When I speak of S+N/N, this is to mean that extraneous detail (fables of mosquitoes, large cars and even larger blimps) only adds noise.

Skip the "extraordinary," stop the fables, and simply state your case. When you remove all this noise, you may discover you are not writing about a quantum system at all, but numbers without meaning. A simple test: what changes its quantum state at 3.5MHz? Is it sub-atomic, atomic, or molecular?

>Richard: Why a "white board"? has a special meaning? - You are
>saying Cecil it is as Dr. House? - Really nice car your RX-7, I envy
>you! - My London friend is "missing2 I owe you some answers :>(

Dr. House refuses to let students write on his white board.

I've driven RXs for 28 years: a 1978 and a 1990 GTU.

London is a nice place to be missing in. I've spent time near Vauxhall bridge in Westminster.

```

'it depends'... in the special case you have concocted where the signal source has no reflections it only takes one round trip. this case is very misleading if you try to extend it to cover other cases. in general it takes infinitely long and you must account for the infinite series of reflections. that is why the approximations used to come up with the sinusoidal steady state solution is so useful, and exactly why it can not be applied to steps and square waves and other non sinusoidal constant sources.

and in your infinite line example it never reaches steady state so the
step wave propagates forever.

'normally' black boxes are just that, opaque elements that you can not measure an internal state with. when you specify a box or something generic with a couple of ports any good engineer will assume that you know NOTHING about what is inside the box, and that you don't care. those type of simplifications are common in engineering methods in order to simplify problems down to the things that you are really interested in... normally BY DEFINITION you don't know and don't care about what is inside 'the box'. so your statement that you know the energy stored in the box is a function of instantaneous flows in and out is non-sequitar, we engineers just don't care and would never try to do a balance like that. if you want to study the energy flow in and out of a box AND the storage of it in the box then provide the circuit for the box and study it properly.

for instance, take your infinitely long transmission line. as an engineer my first action is to reduce that line to a resistor that has a value equal to the characteristic impedance of the line. i can use that equivalent resistor for all calculations for EVERYTHING ELSE in the circuit, but NOT for the internal state of the replacement box.... for obviously if you look in the box and find a resistor dissipating all the power you put into it as heat that will be much different from looking in the box and seeing an infinite transmission line with all that energy propagating forever as an em wave.

if that is all the further you have read then you have much to learn.
at the very beginning they are conjecturing about the possibility of
infinite vs finite propagation velocity, so obviously they have not
made the critical measurements yet to refine the equations to the
proper ones and eliminate all the possible aetheric solutions.

But you are not tracking energy - you are tracking power. As Roy has
said, there is no requirement that instantaneous power must balance.
Where are the stored energy terms in any of your instantaneous power
equations? How do you handle the difference in dimensions between
energy and power? The only condition for which NET power must balance
is during a time interval in which there is zero NET stored power,
e.g. during one cycle.

I have rev'ed my zero interference article to include the following
statement:

"Over a time period of many cycles, e.g. one second at MHz
frequencies, the net average energy and the net average power are
related by joules/second. Thus, if certain conditions are met, net
average power can be used to track the net average energy flow based
on the conservation of energy principle. However, at time intervals of
less than one cycle, as exists for instantaneous power, power cannot
be used to track energy because energy is often stored in a reactance,
is not moving at that instant, and is therefore technically not power.
In fact, unlike energy, power often appears and disappears. There are
special cases where average power in joules/second can be used to
track average energy in joules but instantaneous power is not one of
those special cases."

> From Wikipedia, I have just learned that the concept I am
> attempting to describe is known as a "Continuity equation".

In all your previous equations, you have presented only the first term and completely ignored the second (delta-dot-v) term of the equation which is required for balance. When you add the proper term, i.e. you track and account for all of the energy, your energy equation will balance - as I told you days ago.

> So how do you characterize a slow square wave? Say one that is 0V for
> one year, then 10V for a year, then 0, then...

The same way I characterize, "How many angels can dance on the head of a pin?" The length of time makes absolutely no difference to the concept involved. The above conditions do not match the DC steady-state conditions of your earlier example.

> With an infinitely long transmission line excited by a step function,
> is there an EM wave propagating down the line?

Yes, there is an EM wave at the leading edge. Electrons cannot move at the speed of light. But it is impossible to window such an example in a valid manner because windowing creates other EM waves where none exist in your example. There is no trailing edge in your example yet windowing would necessarily create a trailing edge. Since an infinitely long transmission line is impossible, we are back to the "angels on the head of a pin" problem. In any region of the example where steady-state DC conditions exist, EM waves have ceased to exist. That's what happens when you make the line a fixed length and terminate it at that point. Anywhere DC steady-state conditions exist, your DC forward and reflected wave analysis falls apart.

Your infinitely long open-circuited transmission line example
certainly takes infinitely long to reach steady-state so the leading-
edge EM wave continues forever with zero reflected EM waves and your
argument involving reflected waves falls apart.

Your finite open-circuited transmission line example reaches DC steady-
state where EM waves cease to exist so your argument involving forward
and reflected waves falls apart.

I don't need to track it. I am not the one who is arguing that
instantaneous power is conserved. I have said all along that your
instantaneous power equations were not tracking all the energy. It is
*you* who have not been tracking the energy stored in the capacitor.
When you do that in a valid way, you will discover that the energy
does balance but the instantaneous power still does NOT balance, nor
is it required to balance. IT IS ENERGY THAT IS CONSERVED, NOT POWER!
Please note that the 'Continuity equation' discussion does *NOT* list
power as one of the conserved quantities.

Webster's says an "oxymoron" is self-contradictory. "DC transient
state" would be an oxymoron. "DC steady-state" is merely
redundant. :-)

at the very beginning they
infinite vs finite propagation velocity, so obviously they have not
made the critical measurements yet to refine the equations to the
proper ones and eliminate all the possible aetheric solutions.

You probably have heard about the sulimation of matter and photoemission of electrons,
It means that in the space is the saturated vapour (todays plasma). It is the medium for your radio waves.
It is known from Ludwig Lorenz.

Todays authors are conjecturing about the possibility of the transverse waves. Is it not funny?
What waves are in your transmissing line?
S*

They are photonic waves, obviously subject to the laws of physics that
govern photons.

I see that the stress induced by considering DC waves is causing you to misinterpret my writings.

May I suggest an alternate exploration for you. Assuming that you accept TDR and know how to use Reflection Coefficients to compute voltage and current reflections, then consider what happens when a rectangular pulse is launched from a matched generator in to a transmission line. For simple reflection coefficients like 0, 1, and -1 compute the reflected pulse. For both the forward and reflected direction compute the voltage and current on the line before the pulse arrives, as it passes and after it has passed.

Compute the energy in the pulse, and how long a distance it occupies on the transmission line. Compute the power as the pulse is passing.

Be sure you know what happens to the pulse when it re-enters the generator. For simplicity, assume a generator constructed using the Thevenin circuit.

Make sure all the results are in agreement; especially, the energy delived by the source and the energy dissipated in the various resistors.

Now make the pulse longer and longer... until it looks like a step function. And do the computations again.

Determine if the results agree with those I previously presented for the DC example.

...Keith

PS: Barring errors, they will.

Your mistake here is to assume that because they can sink current that the are sinking DC current. The "ground", as you like to think about it may carry current during the RF cycle, but there is nothing that would cause an unbalanced charge buildup since it IS symmetrical.

You know, he is sort of more amusing than Art. At first. Art can argue
and Art makes no sense, and neither does Szechuan, but he can't build an
argument that even sounds a little bit logical. And his arguments never
change. Art makes up new stuff all the time.

Prediction - Szechuan will eventually become so boring no one that no
one will respond.

And I forgot to include that there is no field emission, so no charge
could possibly build up.

Your mistake here is to assume that  the RF cycle,  IS symmetrical.

Each real wave is asymmetrical. The forward pulse is always stronger than
the return.
For this reason you must have power on.

Emission is the result of voltage.

If the power is ON the emissin take place.

Each one of you can measure the DC ground current.
Why you  are so boring sending the same incontructive answer (no emission).
Emission is a fact. It is interesting how it is much.

why would i want to do all that work? there is no way that my answers will agree with your misconceptions. you'll just come up with an even uglier generator to try to make it fit.

oh, and by the way, your fancy 2 generator and 2 resistor 'constant power' source isn't what you think it is. go back to basic circuits 101 and you will find that any linear network like that can be reduced to either a simple one source one impedance norton or thevenin equivalent. in your example it is identical to a 50v voltage source in series with a 50ohm resistor... deriving the norton equivalent is left for the student.

first, the fcc would get really mad at me if my rf waves weren't
symmetric,  that would make for horribly distorted signals!

and yes, i have measured the dc ground current and it is also zero.
when you have a transmitter in your car are the rubber tires not
isolating the car body from ground?  do you get shocked after you have
been transmitting for a while and step out of your car?  where does
the ground current go when you have a plastic cased handheld radio?

i agree, mr. b is not as much fun as art... at least he made up things
that weren't so easy to observe as wrong, after all who could see the
waste deep levitating neutrinos jumping off their diamagnetic
```

antennas. mr. b's stuff is just absurd.

On Jun 25, 4:00=A0pm, Keith Dysart <keith.dys...@gmail.com> wrote:

> That's the time domain. Variation in the instantaneous energy flow.

What you seem to be missing is that the *energy content* of power (total joules) must be conserved but the instantaneous power (joules/second) does not have to be conserved as you have argued numerous times in numerous examples. The only question that needs to be answered is: In a system designed to eliminate reflections and interference, does all the reflected energy eventually get dissipated in the source resistor. The answer is yes because there is nowhere else for it to go. There is no conservation of power principle and that includes instantaneous power. So it is irrelevant what/where instantaneous power might do/go during a single cycle.

Now I understand that instantaneous power dictates some physical design considerations as in waveguides. But since instantaneous power does not fall under the conservation of energy principle, it is simply irrelevant to the present discussion. What happens over a complete cycle is what is relevant. However, in any and every case, it is energy that is conserved, not power. How many joules are in that dt sliver of time when the instantaneous power is 100 watts? It's those joules that must be conserved, not the instantaneous power.

You didn't answer my previous question. If you measure 100 watts of instantaneous power at 100 places within an inch of each other, does that mean there is 10000 watts of instantaneous power in that one inch of wire? That is the only logical conclusion based on your argument and assertions. Any argument based on the conservation of power is doomed to fail. Please get real.

> Not quite
> 'as useless as tits on a boar hog, or as Hecht said, putting it
> mildly: "of limited utility"'.

One could argue that tits on a boar hog are not completely useless and, therefore, instantaneous energy is exactly as useless (or exactly as useful) as tits on a boar hog. (Hint: Without the existence of the tit gene in the male, female hogs would probably not have tits.)

Nobody except you, using instantaneous power, has attempted to superpose power. The Power-Density/Interference equation does NOT superpose power because it contains the interference term. If the interference term were omitted than it would be an attempt to superpose power, but I have never omitted the interference term except when it was zero.

On Jun 25, 7:07=A0pm, Keith Dysart <keith.dys...@gmail.com> wrote:
> Using superposition, when you add Vrev2(tau) to Vfor1(rho) you get
> zero. With zero voltage comes 0 energy transfer.

Completing your above sentence: With zero voltage comes 0 energy transfer *in the direction of travel of the original waves that were superposed*. Assuming that you believe in the conservation of energy principle, what happened to the energy in the two component voltage waves necessary for their existence before they cancel each other? If they didn't contain any energy, they would be zero but we know they are not zero, i.e. they are 35.7 volts each. That original wave energy is redistributed and *transfered* in the opposite direction, the only other direction available in a transmission line.

One cannot argue with a forked tongue that the superposed waves never existed in the first place because that would violate the laws of physics and superposition.

> Do you really need rho^2 to understand what goes on in a transmission
> line?

Not using rho^2 is why you are so confused. If you actually cared where the energy goes, you would be forced to use rho^2 or at least multiply the superposition component voltages and currents to obtain the power in the superposition component wavefronts.

In the earlier example, the impedance discontinuity has a physical voltage reflection coefficient of 0.7143 and a physical power reflection coefficient of 0.51. If you consider the steady-state power conditions, you will calculate a virtual power reflection coefficient of 0.0 and a virtual voltage reflection coefficient of 0.0. Which reflection coefficient is correct? Obviously, physical trumps virtual every time.

The 50v source voltage reflected at the 0.7143 reflection coefficient is 35.7 volts and it exists in a 50 ohm environment. Simple math yields the power =3D (35.7)^2/50 =3D 25.5 watts. Where did the energy in that 25.5 watt EM wave go? One can obtain the same value by calculating the current: 1a(0.7143) =3D 0.7143. Power =3D 35.7(0.7143) =3D 25.5 watts.

So you can get by without using rho^2 but to determine where the energy is going, one needs to at least multiply the EM traveling-wave voltage by the EM traveling-wave current (or calculate the ExH Poynting vectors).

In fact, this would be a good application for your instantaneous power calculations. Where is the energy going that is in the instantaneous power being reflected by the impedance discontinuity?

Each waves transports mass in direction from the source. This is form of
asymmetry.

>and yes, i have measured the dc ground current and it is also zero.
when you have a transmitter in your car are the rubber tires not
isolating the car body from ground?

You do not read my posts:
""The use of the term ground (or earth) is so common in electrical and
electronics applications that circuits in portable electronic devices such
as cell phones and media players as well as circuits in vehicles such as
ships, aircraft, and spacecraft may be spoken of as having a "ground"
connection without any actual connection to the Earth. This is usually a
large conductor attached to one side of the power supply (such as the
"ground plane" on a printed circuit board) which serves as the common return
path for current from many different components in the circuit."

>do you get shocked after you have
been transmitting for a while and step out of your car?

It is common event.

> where does
the ground current go when you have a plastic cased handheld radio?

To chassis. See the chassis ground.

>i agree, mr. b is not as much fun as art... at least he made up things
that weren't so easy to observe as wrong, after all who could see the
waste deep levitating neutrinos jumping off their diamagnetic
antennas. mr. b's stuff is just absurd.

Radio was made by Stokes, Helmholtz and Tesla.
I try to remember it to you.

In the radio area it is nothing to do.
Everything was done by Stokes, Helmholtz and Tesla.
Radio people should know a little about them.

The first step should be measuring the DC ground current.

"(II) Field emission: In this method, a strong electric field (i.e. a high
positive voltage) is applied at the metal surface which pulls the free
electrons out of the metal because of the attraction of positive field. The
strong the electric field, the greater is the electron emission. "

You are incorrect.

that quote is correct... unfortunately the voltages created by most
radio transmitters aren't high enough to overcome the metal work
function so no field emission takes place from antennas.  and even if
it did it wouldn't go anywhere because radio waves are symmetric.

All begin reading the advice of a reseller on a Italian ham magazine, that claim this (translated):

"The MFJ 1796 antenna only at XXX euro !!! 2,6,10,15,20,40 meters Superior Half-Wave configuration !!"

Oh well, i'm really a rookie on antenna theory, but - thinking into myself - someone at MFJ can please explain me what the hell make on this antenna to shrink an half wave antenna on 40 meters into a stick shorter than quarter wave??

Before posting the question on this NG to learn more, a look on MFJ site and i read on the description:
"Full size halfwave on 2/6 Meters."
Ah right, someone here in Italy forget to specify *where* is 1/2 wl designed :)
But the funny thing is not what i tell until now... the funny (or sadly) thing is that 7 local hams over 10, asking them if on 40 meters perform well the MFJ 1796 or a common quarter wave antenna, reply "the 1796 for sure ! Is a half wave designed antenna" someone adding also " you know antenna theory, not ??"
Of the remaining 3 hams, 2 of this 3 replied with approximately my same doubt ("what?? an half what ??")
A special mention to the last one that replied the dipole is the only antenna that he consider. He said that vertical antenna is the best system to deliver half or more applied power to the earth, no matter how is designed. So he don't ever read the advice and don't reply to the original question :)

```
...
Well, marketing and language misuse can add gain on an antenna, now i know
this :)

Sorry for my english, i hope that the sense of the story is clear to
readers.

I previously had a senior moment and changed contexts in the middle of a posting and I apologize for any confusion. Would you enlighten me as to the area of the discussion that you don't catch? Do you understand physical reflection and transmission coefficients and their effect on voltage, current, and power?

It would be an opportunity for you to deepen your understanding of the
behaviour of transmission lines.

> there is no way that my answers will agree with your misconceptions. =A0

I am not convinced. You have not yet found any errors in my
expositions,
so if you do not make any errors, I expect we will agree on the
outcome,
though perhaps not on the interpretation, for you disagree when I say
"do not assign TOO much reality to the energy in reflected waves.

You seem to want your reflected waves to always transport energy, but
are unhappy that this leads to a line that was originally excited with
a step function having energy flowing in both directions even though
the current is zero all along the line.

Cecil simply sidesteps these little inconveniences by refusing to
consider anything other than sinusoidal RF excitation and by
refusing to consider any time based analysis. Such is not the path
to understanding, deep or otherwise.

> you'll just come up with an even uglier generator to try to make it fit.

My generators are pretty simple. So far I have only used 3: Thevenin,
Norton, and one with an interesting constant input power
characteristic.

> oh, and by the way, your fancy 2 generator and 2 resistor 'constant
> power' source isn't what you think it is. =A0go back to basic circuits
> 101 and you will find that any linear network like that can be reduced
> to either a simple one source one impedance norton or thevenin

> equivalent. =A0

You have confused a bit, models with implementation. As I said in the original: "Consider a generator constructed as below". I am not using an equivalent circuit, but a construction. Only when dealing with the actual construction is it valid to examine the internal energy flows. An "equivalent" circuit is equivalent for external behaviour but not necessarily for internal, so I avoid them when examining the internals.

...Keith

but the equivalent points out that your statements about it sourcing
constant power is incorrect.
```

i have also pointed out that your statements about your 'step wave' are obviously incorrect because you have applied assumptions that are only valid in the sinusoidal steady state to a step function that can never be in steady state. neither can your pulses for that matter, so all the assumptions are worthless, you must do the complete analysis including the summations for the infinite fourier decomposition of your step or pulses to get the full picture... in a transient analysis. as was pointed out if you go VERY far into the future with a battery connected to an open circuit piece of coax there can be no currents and therefore no waves propagating in the line. its only in the detailed transient analysis that you haven't done where you will see the propagating steps going back and forth.

That's simply false. Using Fourier analysis, I reduce anything other than a sinusoid to multiple sinusoidal RF excitations, perform the sinusoidal analysis, and then use superposition to find the answer. I also reject any example where Maxwell's equations do not work. Your insistance that magical waves can somehow exist during DC steady-state violates the known laws of physics. EM waves CANNOT exist during DC steady-state because electrons are traveling at a constant velocity. You can measure DC voltage with an AC voltmeter but that doesn't change DC voltage to AC voltage.

In any region, the energy flowing in (i.e. power) to the region minus
the energy flowing out (i.e. power) is equal to the additional energy
per unit time (i.e. power) being stored in the region. While not
called the "conservation of power law" it is an obvious corollary
to "conservation of energy".

> The only question that needs to be
> answered is: In a system designed to eliminate reflections and

> else for it to go.

The obvious alternative is that the computed energy in the reflected
wave is sometimes just a figment. Or is something else happening with
the step function example?

Not to mention that in your 1/8 wavelength example (http://
www.w5dxp.com/nointfr.htm)
you do not explain where the energy is stored so that it can be
returned at a different time.

> There is no conservation of power principle and
> that includes instantaneous power. So it is irrelevant what/where

Such declarations do permit an easy out, despite not aligning with
reality.

> Now I understand that instantaneous power dictates some physical
> design considerations as in waveguides. But since instantaneous power
> does not fall under the conservation of energy principle, it is simply
> irrelevant to the present discussion. What happens over a complete
```

> cycle is what is relevant.

If that is the case, the whole concept of reflected energy seems
somewhat bogus. Over a whole cycle, the power delivered by the
generator is passed on towards the load. If that is all you want
to know, then there is no need at all for "reflected power".

> However, in any and every case, it is energy that is conserved,
> not power.

Yes. But see the related corollary above.

> How many joules are in that dt
> sliver of time when the instantaneous power is 100 watts? It's those
> joules that must be conserved, not the instantaneous power.

Still having problems with mapping the concepts from calculus to the
real world, I see.

> You didn't answer my previous question. If you measure 100 watts of
> instantaneous power at 100 places within an inch of each other, does
> that mean there is 10000 watts of instantaneous power in that one inch
> of wire? That is the only logical conclusion based on your argument
> and assertions.

No more than "If you measure 100 watts of *average* power at 100
places
within an inch of each other, does that mean there is 10000 watts of
average power in that one inch of wire?"

But it is a way of thinking that you like to use to distract
yourself from the really interesting results.

> Any argument based on the conservation of power is
> doomed to fail. Please get real.

Please study the corollary above.

So which is it? Is instantaneous energy flow a useful concept? Or is
it
not? You previously suggested an understanding of the value (when I
mentioned "real power folk"), but seem to continue to want to argue
its complete lack of usefulness.

And to stop besmirching Hecht, it seems most probable that his comment was in the context of optics. After all, the book had that title.

That does present a bit of a challenge to decipher.

Try using groups.google.com to read the message.

After opening the topic, scroll to the top and click "Options" which
should be found in the same header as the Topic. Click "Fixed font".

This significantly improves readability.

The fundamental question is: "did they have energy?"

Let us express this as a hypothesis:

Hypothesis 1: The component voltage waves have energy.

Then it should follow that we can trace this energy and discover where it goes.

At least three examples have been proposed where the energy can not be properly traced:

Example 1: Step function applied to a transmission line. After the line settles, a forward and reflected voltage wave continue on the line but no energy is being transferred.
Example 2: On a line with infinite VSWR no energy crosses a voltage minimum or maximum.
Example 3: With the 1/8 wavelength line described in http://www.w5dxp.com/nointfr.htm the energy can not be properly accounted for on a moment by moment basis.

Only one counter-example was needed to disprove the hypothesis, three have been found. There may be more.

Hypothesis is disproved.

No matter how many examples are found that support the hypothesis, the hypothesis is still disproved.

...Keith

Thanks Cecil:

Examples of you that I saw in recent weeks were about interferences generated by a single real generator and reflections, resulting, for example, in constructive/destructive interference responsible of changes in energy flow direction starting from the line point where those interferences occurs. In a nutshell: In post 127 I asked you for an example/experiment based in TWO real generators to assimilate it to more familiar double slit interference phenomenom (TWO coherent sources) rendering energy redistribution inside one dimensional TL space, two sources in tridimensional space gives maximuns and nulls on screen (redistribution). Well, I ask you for identical example in unidimensional space rendering a phenomenom similar as reflection (one wave) but with interference (two waves). Sorry I do not know how better translate my question to english words.
I not catched your answer because it does not match my question :>)

Thank you very much in advance. Miguel - LU6ETJ

I'm sorry, that is simply not true for power. The energy content of a 1us pulse containing one joule and the energy content of a one sec pulse containing one joule are equal and that one joule is all that must be conserved. The 1us pulse containing 1,000,000 watts can be converted to a one second pulse containing 1 watt. Where did the other 999,999 watts go??? Energy has been conserved but the power changed from 1,000,000 watts to 1 watt using exactly the same energy. Perhaps this characteristic of power is what you are missing. Also, all the energy can be conserved in reactance while power falls to absolute zero. This often happens during a fraction of a cycle. That is what is wrong with you trying to track instataneous power - it doesn't work unless one standardizes to at least one cycle. Within each fraction of a cycle, any principle of conservation of power will surely be violated. If it appears that power is ever conserved, it is only by accident. Such is the case with many megacycles/second where the result of a fraction of a cycle will have a negligible effect on the joules/sec.

> The obvious alternative is that the computed energy in the reflected
> wave is sometimes just a figment.

And God created the heavens and earth in six days and rested on the seventh. I'm glad you are happy with your faith-based physics. In the field of real-world physics, EM waves cannot exist without ExH energy. The only way to win this argument is to prove to everyone that they are not really detecting reflected waves containing energy when they look at themselves in the mirror. Good luck on that one.

Question: How were the first three days measured before the creation of the sun on the 4th day?

> Not to mention that in your 1/8 wavelength example (http://www.w5dxp.com/=

nointfr.htm)
> you do not explain where the energy is stored so that it can be
> returned at a different time.

Energy is stored in the transmission line and delivered as needed to satisfy the conservaton of energy principle. Years ago, I showed how energy can flow *into the source* (negative power) during a fractional part of a cycle in a conjugately matched system.

> Such declarations do permit an easy out, despite not aligning with
> reality.

If you can take one joule per microsecond (1 megawatt) and conserve that one megawatt of power over a century, you can get rich selling it. Let us know when you get your patent on conservation of power. :-)
Good Grief!

But, as you can grok from the subject of this thread, that is not all that is needed to know. The last gasp of the loser is that it didn't matter anyhow. Reflected energy has always mattered to optical physicists who know it obeys the laws of physics. Now it seems to matter to some hams. If it doesn't matter to you, why do you continue posting?

> And to stop besmirching Hecht, it seems most probable that his

> title.

Hint: RF waves are covered in every physics book whose title is "Light". There is absolutely no difference, from a physics standpoint, between a coherent light wave and a coherent RF wave except for frequency. The both obey exactly the same laws of physics which you seem to concede for visible light but not for light at RF frequencies.

As far as I am concerned, if Maxwell's equations don't work on an example, it might as well be ignored. There is nothing during DC steady-state that allows Maxwell's equations to work because there are no EM waves during DC steady-state. Why don't you already know that?

I can take your approach and do you one better. Please prove that you exist. If you cannot prove that you exist, then nothing you say is of any consequence. See, I can do it also.

> Example 2: On a line with infinite VSWR no energy crosses a
> =A0 =A0 =A0 =A0 =A0 =A0voltage minimum or maximum.

Completely false assumption. You are back to asserting that since the north-bound traffic equals the south-bound traffic on the Golden Gate Bridge that there is no traffic and no bridge maintenance is required. When are you going to give up on that irrational wet dream of yours? No *NET* energy crosses at a voltage zero or current zero point. That

doesn't make the north-bound energy equal to zero and doesn't make the
south-bound energy equal to zero. It just makes them equal. Just
because there is no NET traffic flow on the Golden Gate Bridge doesn't
mean there is zero traffic flow in both directions. Please stop
clowning around with such absurb notions.

 be
> =A0 =A0 =A0 =A0 =A0 =A0properly accounted for on a moment by moment basis=
.

There is no conservation of power principle. If you would track the RF
joules and the conversion of RF joules to heat instead of the joules/
second, everything would become clear to you. As it is, you are
laboring under some serious misconceptions about the laws of physics.
Power simply doesn't balance within a single cycle - because it
doesn't have to - because there is no conservation of power principle.

People who don't learn from their mistakes are doomed to commit the
same mistakes over and over. Keith, you seem to be all output and no
input. Please enable your input channels for a change.

You might like to actually test it. The two sources are always delivering 100W.

With an open circuit load:
The current source is delivering 100 W to the parallel source resistor.
The voltage source delivers nothing.
Total: 100W

With a shorted load:
The voltage source is delivering 100W to the series source resistor.
The current source delivers nothing.
Total: 100W

With a 50 ohm load:
The voltage source is delivering 50W.
The current source is delivering 50W.
Total: 100W
The load is receiving 50W.
Each generator resistor is dissipating 25W.

> i have also pointed out that your statements about your 'step wave'
> are obviously incorrect because you have applied assumptions that are
> only valid in the sinusoidal steady state to a step function that can
> never be in steady state.

I am not sure where you think there is an error. Perhaps you can point them out in the following example:

Generator:
- 100V step in to an open circuit
- 50 ohm source impedance

Line:
- 50 ohm
- open circuit

Generator is commanded to produce a step.
This will produce 50 V and 1 A at the line input which will propagate down the line.
The open end of the line has a reflection co-efficient of 1.0.
Just before the 50 V step reaches the end of the line, the whole line will be at 50 V and 1 A will be flowing everywhere.
The 50 V step hits the end and is reflected, producing a 50 V step (on top of the 50V already there) which propagates back to the generator. In front of the 50 V step, the current is still 1 A (which provides the charge necessary to produce the reverse propagating 50 V step. Behind the step, the current is 0.
When the reverse 50 V step (which is actually a step from 50V to 100V) reaches the generator, the source impedance matches the line impedance so there is no further reflection.
The line state is now 100V and 0A all along its length.

The settling time was one round-trip.

The generator is still producing the step, so the forward step voltage wave is still 'flowing' and being reflected so there is still a reflected step voltage wave, each of 50 V.

Since the generator open circuit voltage is 100 V and the line voltage is now 100 V, current is no longer flowing from the generator to the line.

Does this agree with your understanding?

I have snipped the rest of your post since until the above is agreed, there is no sense in proceeding further.

...Keith

It is easy to put anyting on paper. Antenna gain advertisement was so bad that many years ago the ARRL would not let anyone put gain numbers in their advertisements.
Most things made by MFJ are not very well thought of in the US.

That's why it's referred to as "Mighty Fine Junk" remember the V31BB
Mighty Fine Junk network? Too damn funny.

You need to expand your solution space. Some problems are so much easier to solve in the time domain.

I can't even imagine doing some problems in the frequency domain. Let's see: I turn on my flashlight maybe once per week, so the fundamental is 1.6e-6 Hz, and say the risetime is 1 millisecond -- my head hurts already -- that's about 600,000,000 harmonics to be computed. No wonder you give up on some problems so readily.

> I also reject any example where Maxwell's equations do not work. Your insistance that magical waves can somehow exist during DC steady-state violates the known laws of physics.

It is not my insistence. It follows from the math.

Besides if you convert it to the frequency domain you should be happy that they exist since they then align with your understandings.

> EM waves CANNOT exist during DC steady-state because electrons are traveling at a constant velocity.

Are you sure you meant this? The electron velocity changes? Or did you mean the wave velocity? Nope. That does not work either.

> You can measure DC voltage with an AC voltmeter but that doesn't change DC voltage to AC voltage.

And for especial fun... Why are you sure DC is so special?
  v(t)=3DA cos(wt)
describes a sinusoid. It has the parameter w to specifiy the frequency. Set it to 0, and voila: DC. It falls right out of the same definition as is used for a sinusoid. It is a sinusoid.

Sorry, I ommited aknowledge to you I understoond your example and
what you mean with:

"What happens to Vfor1(rho) = 50v(0.7143) = 35.7v? "
"What happens to Pfor1(rho^2) = 50w(0.51) = 25.5w? "

(Last represent the cancellating (interference?) term of transmitted
power (1.Rho^2) towards generator from the reflected power from the
load to render VRef1=0 (doing the accounts with phasorial V-I math,

though I suppose will give similar results employing the eq-1 of your
World Radio article, but I am not sure if I'm catching it very well
yet. Have you P1, P2, P3 and P4, for your 100 W example, to clear
it?)

Miguel

Perhaps some of your difficulty is revealed in your phraseology. A
pulse does not 'contain' power. It can deliver energy at some rate.
If the pulse is rectangular, the rate will be constant for the
duration of the pulse. With some other profile, the rate will
vary over the duration of the pulse.

Perhaps a simple analogy would help. Near my house is a 50 m water
tower with a bunch of pipes connected to the bottom. The rate at
which water is added to the tower is always equal to the sum
of the rates flowing in on all the pipes (assume positive flow
raises the level in the tank, while negative flow reduces it).

Rephrased, for greater certainty: At any instant in time, the
rate at which water is being added to the tower is always equal
to the sum of the rates flowing in on all the pipes.

At any instant in time, all the water (and flows) can be
accounted for.

Same for energy (and energy flow).

Some do say, but this appears to be rather a non-sequitor.

> I'm glad you are happy with your faith-based physics. In the

Perhaps, then, you are simply arguing that these are not EM waves
since they do not have ExH energy?

Continuing with non-sequitors?

Nope. That also failed to account for the energy when observed in the
time domain. See http://sites.google.com/site/keithdysart/radio6.

Several differences:
- Transmission lines work down to DC
- At lower RF, it is possible to independantly measure voltage and
  current

This allows a better understanding of the behaviour, not constrained
by the capabilities of the mearsuring instruments.

...Keith

I always thought that Maxwell's equations were more complete than that
and worked all the way down to DC. Two of them do not even include
time
and nothing says that a derivative with respect to time can't be 0.

I suppose, but then you have to give up on P(t)=3DV(t)*I(t), generally
considered to be a rather fundamental equation.

There is no mention of power above; simply energy.

Are you saying that conservation of energy only applies some of
the time?

In your example, the RF energy does seem to disappear and re-appear,
when tracked on a moment by moment basis.

> It is not my insistence. It follows from the math.

Unfortunately for your arguments, math models do not dictate reality.
If the math model doesn't match reality, it is invalid. Your math
models obviously do not match reality.

> Are you sure you meant this? The electron velocity changes? Or did
> you mean the wave velocity? Nope. That does not work either.

Yes, acceleration and deceleration of electrons (in the conductor) is
required for EM waves to even exist. That's an obvious change in
electron velocity. Is that another fact of physics that shoots your
theory down? I repeat: EM waves are impossible during DC steady-state.

> From the above, you have proved that I exist. Thank you.

Nope, I believe you are only a figment of my imagination. Please prove that you actually exist.

> I suppose, but then you have to give up on P(t)=3DV(t)*I(t), generally
> considered to be a rather fundamental equation.

I have absolutely no problem with giving up on the conservation of power principle in which no rational technical person can possibly believe.

> Are you saying that conservation of energy only applies some of
> the time?

No, I am saying that if you cannot balance the energy equation at all times, you have made a mistake. You are not tracking joules. You are attempting to track watts which can appear and disappear at any time. The only condition where watts can be tracked is over an integer multiple of complete cycles. That's why watts can be tracked when the frequency is in the MHz. Trying to track instantaneous watts within a fraction of a cycle is a moronic attempt at power superposition, a no-no that we all learned in EE101.

> In your example, the RF energy does seem to disappear and re-appear,
> when tracked on a moment by moment basis.

No, the power can disappear and re-appear but the energy cannot. You have not even come close to tracking the energy.

> Well, it would help if you could actually find and articulate a flaw
> inhttp://sites.google.com/site/keithdysart/radio6.

The flaw is your belief in a conservation of power principle that doesn't exist. Instantaneous power is not required to obey any conservation principle. What you are doing on that web page is attempting to superpose powers apparently without a clue.

Superposition of power is a no-no. The power density equation allows us to accomplish the addition of *average* powers taking interference into effect. I know of no such mathematical equations for instantaneous power and your instantaneous power superposition technique is obviously invalid.

P1+P3 =3D Pfor1 =3D 100w

P2+P4 =3D Pref2 =3D 104.1w

Yes, those look like close to the correct values. I guess I should add
them to my article.

The MFJ products that I have purchased and use work well for me.
Judging from their popularity and growth, I am not the only one who
can make their products work.

of course they do constant electric field and constant magnetic fields
work just fine and go out to infinity in the dc steady state case.
this of course means there can be no moving electrons, therefor no
current, no d/dt terms, etc... which means no waves.

very fundamental, and very restricted. only good for one point in
space at one time, and for one pair of voltage and current
measurements... can not be applied to separate waves that are
superimposed, only to the final total voltage and current at the
measurement point at that instant.

when doing conservation of energy you must include the WHOLE system!
it doesn't work on one section of a transmission line any more than it
works for the infamous undergraduate teaser:

take a refrigerator, put it in a perfectly insulated room, and then
open the doors... what happens to the temperature in the room?

that site is rather worthless... you say Vs can be used to get the
time reference for the other signals, but time is a variable, as is
space. you seem to have a snapshot of a bunch of sine waves on an
angular scale, but is that scale time or distance?

Each wave transports the mass and energy from the source (or mirror).
In the microwave oven the all energy is transfered into heat.

In antenna the part of energy and mass is emitted. The reflected part is smaller.

```

A helically-wound dipole or monopole that is physically short in terms of a free-space wavelength can be made electrically resonant at its input terminals as a result of the inductance of the helical form of the radiating conductor.

But that does not mean that it has all of the electrical characteristics of a linear conductor that is inherently resonant, without the need for inductive loading.

The radiation resistance of such a helically-wound radiator can be much lower than a naturally resonant radiator, which can mean that the percentage of transmitter power radiated by the antenna SYSTEM can be much lower than when a naturally resonant radiator is used.

The link below leads to a page developing this point from Kraus' Antennas For All Applications, 3rd Edition.

  http://i62.photobucket.com/albums/h85/rfry-100/Helically-woundVertical.gif

If the cosine term is zero, there are zero EM waves, either forward or
reflected, and your argument falls apart.

Incidentally, V(t) =3D 10, is a perfect way to prove that energy and the
time derivitive of energy are not the same thing and your argument
falls apart.

Windowing doesn't generate EM waves where none exist in reality and
your argument falls apart.

a better argument is that a constant voltage produces a constant
electric field everywhere, since the field is not varying in time or
space there is no time or space derivative to create a magnetic field
so there can be no propagating em wave.  you could do the same with
```

zero or constant current producing a constant magnetic field.

essentially the dc case IS unique in that you must wait forever for it
to reach sinusoidal steady state since the lowest frequency component
is 0hz.

Yes, replying to Richard but also to Roy and Dave.. maybe i can't explain very well, but the sense of my latest question is this:

if a half wave end-fed *monopole* antenna have the following primary characteristics (if IIRC):

- High Z at the feedpoint (voltage maximum and current node);
- very small counterpoise lenght compared to the resonant wavelenght of the antenna (typical 0.1-0.2 lambda)

can i mantain the same characteristics shortening the antenna in any way ??

Thanks for read and explain to those who want clarify my doubts.

Google EZNEC and find Roy's site.
Download & install the demo version- it is free!
Go through some of the simple examples like dipoles, 1/4 verticals
etc.
Bring your questions back to this group and we will all benefit.

Antennas are pleasantly addictive!
I consider myself a perpetual student...

One too many words - what I meant to say is that you are not adding up the energy - you are adding up the power. There is no such thing as conservation of energy flow. That is proved by your own graphs. There are times when the energy flow is destroyed. There are other points on your power graphs where energy flow is created.

> There is no conflict with conserving flows, ...

The conflict is that conservation of flows doesn't exist. Keith, you
need to go back to college. There is no such thing as conservation of
energy flow so your argument falls apart. When one looks up
"conservation" in a physics book one finds:

conservation of energy principle
conservation of mass-energy
conservation of mechanical energy
conservation of momentum principle

There is NO conservation of energy flow or conservation of power.
Until you give up on that ridiculous concept, we don't have much to
discuss except your religion.

> > What happens when energy =3D 1 joule, and de/dt =3D 0 watts. This happe=

> > is still present.
>
> Yes, indeed. That is a fundamental possibility and occurs on
> transmission lines with infinite VSWR.

If power goes to zero, power has been destroyed. Therefore, there is
no conservation of power principle. Anything that can go to zero, i.e.
can disappear, cannot be conserved.

> Power is the time derivitive of energy. They are related
> but definitely not one-to-one.

Well, that shoots your argument down. If power and energy do not have
a one-to-one correspondence, then you cannot use the conservation of
energy principle to prove that power is conserved and your argument
falls apart. You must then product a conservation of power principle,
something that every physics professor has warned us doesn't exist.

I can provide any number of references to support the conservation of
energy principle. Please provide just one bona fide reference that
supports your conservation of energy flow (power) principle.

> This is quite incorrect. Energy flows must balance, otherwise energy
> is being created or destroyed to sustain a difference in flow.

Good grief! Any physicist knows that is false. Any number of examples
prove that is false.

> Energy flows must balance as well. Otherwise,
> energy is coming from nowhere to sustain the flow.

Given a black box with an input and output. Measurements of the power flow vector indicates that the magnitude of each power flow vector is 50 watts and both vectors are pointing inside the black box. How can the instantaneous energy flows possibly balance?

> Instead, think that at every instant, the energy flow between the entities in the experiment must balance.

You are contradicting yourself. Assume the capacitor *IS* the system inside a black box. The instantaneous energy flow does NOT balance.

> It is the total energy within the system that is conserved, just as it is the total of the flows of energy between the entities within the system that must be conserved.

You have it half right. Energy must be conserved. Energy flow is not conserved.

> Put more strictly: The sum of all the energy flows in to all of the entities within the system must equal the energy flow in to the system.

Please see the black box experiment above and balance the energy flow.
Please produce a reference for the conservation of power principle.

Translation: Don't bother me with technical facts based on the laws of physics. I am perfectly happy with my present metaphysics.

Actually, recognizing that EM waves are photonic in nature and are therefore bound by the laws of physics governing photons is an attempt to correct the previous years of misdirection engaged in by some RF gurus. Such concepts as zero energy in EM reflected waves comes to mind. If EM reflected waves do not obey the laws of physics, then they don't exist - but they do.

> I think this is the genesis of Cecil's view that energy waves
> somehow bounce off the standing wave node.

I'm sorry, Roy, but I never said anything of the sort. Keith apparently believes that energy waves somehow bounce off a standing wave node. I am on the opposite side of that argument. I believe that the forward wave and reflected wave flow right through a standing wave node. I am on record as saying the only time a reflection occurs is at a physical impedance discontinuity.

Misdirection is also accusing someone of saying something that they never said, is a low blow, and is not an ethical act.

If that is true, then why is there a pacemaker warning posted around
many microwave ovens in public places? Doesn't that warning imply that
not all energy is transfered into heat?

??

With proper design you can maintain the resonance characteristic with
that short antenna, but not its characteristics of SWR bandwidth,
exact radiation pattern (directivity), or radiation resistance.

For a single frequency the only important difference will be radiation
resistance, unless the short radiator is used with a virtually perfect
(zero loss) ground plane.

A typical r-f ground loss even in a set of 120 each, 1/4-wave-long
buried radials is on the order of two ohms. So referencing the
example in the link to Kraus that I posted earlier, the radiation
efficiency of that helically-loaded monopole system with a two ohm r-f
ground would be about 0.6/2.6 =3D 23%, approximately.

The loss of a radial system using 0.1-0.2 lambda conductors would be
significantly higher, so the antenna system radiation efficiency then
would be significantly less than 23%.

A naturally-resonant, unloaded monopole about 1/4-wave high has a
radiation resistance of around 34 ohms. When it is used with a two
ohm r-f ground, the radiation efficiency of the antenna system is
about 34/36 =3D 94%.

You say lasers are not coherent and then post the url containing
"Description: Free Electron Laser Diagram"?

Free electron laser it is a quite different thing than laser.

The free electron laser produces the "laser-like" light:

" As the electrons are undergoing acceleration they radiate electromagnetic
energy in their flight direction, and as they interact with the light
already emitted, photons along its line are emitted in phase, resulting in a

"laser-like" monocromatic and coherent beam". From:
http://en.wikipedia.org/wiki/Halbach_array

I do my best.

May be the Wiki is better: "The electron temperature of a plasma can be several orders of magnitude higher than the temperature of the neutral species or of the ions. This is a result of two facts. Firstly, many plasma sources heat the electrons more strongly than the ions. Secondly, atoms and ions are much heavier than electrons, and energy transfer in a two-body collision is much more efficient if the masses are similar."

You know: The Sun produces the plasma (it rotate with the Sun) and the plasma is a medium for the longitudinal electric waves (Tesla - the father of the radio). Is not it funny?

But a helically-wound radiator *is* a naturally resonant radiator if
wound to make it so. It just isn't straight.

Although 2 ohms is a reasonable approximation for 120 radial ground
system resistance, it varies not only with ground quality and frequency,
but also antenna height. For example, an NEC-4 simulation for vertical
radiators at 3.7 MHz with 120 radials, each a free space half wavelength
long buried 0.1 meter in average soil, shows 3.25 ohms ground system
resistance when the radiator is 0.24 wavelength high (nearly resonant).
When the radiator is shortened to 0.12 wavelength, the ground system
resistance increases to 4.30 ohms. And with a 0.06 high radiator, the
ground system resistance nearly doubles to 8.06 ohms. This decreases the

efficiency of the very short radiator by about an additional 3 dB beyond what it would be if the ground system resistance were fixed at 3.25 ohms.

I believe the ground system resistance increase with short radiators is due to concentration of the field very close to the antenna, resulting in much higher ground currents in that region. It would probably be useful to use a larger number of radials, which could be shorter, when the radiator is very short.

You can add a top hat to a vertical that's shorter than a half
wavelength, and bring it to anti-resonance (high input resistance with
no reactance). The impedance won't be as high as if the antenna were a
half wavelength high, and it will have narrower bandwidth, so it won't
be a perfect imitation. Or you can use a combination of loading
inductance and top hat to get a somewhat poorer imitation.

That is true, but a resonant, helically-wound, electrically short radiator does *not* have the radiation resistance of a straight, self-resonant radiator of about 1/4 wavelength -- which can make a large difference between the two forms in the amount of available energy radiated vs. that lost in the r-f ground system.

Guess I just don't understand how a resonant, helically-wound antenna is
"electrically short". Suppose you helically wound an eighth-wave
vertical in such a way that it was resonant. Its physical length is an
eighth wavelength. What would its "electrical length" be? That is, how
"electrically short" would it be?

How do you determine what the "electrical length" of a vertical or
dipole is? Does a loading coil at the base alter the "electrical
length"? Does an L network at the base?

Its overall height in free space wavelengths. This is the definition used by the FCC for the unloaded monopoles used in AM broadcasting

Do you expect your 1/8 WL high, self-resonant helical to have the same electrical length and feedpoint parameters as a self-resonant, straight radiator about 1/4 wave high in free space wavelengths?

According to Kraus and other authors, your example above still has about the same radiation resistance as a 1/8 WL straight conductor -- not that of a self-resonant, straight conductor about 1/4 WL high.

An 1/8 WL high helical may be resonant, but it will not perform the same in a practical antenna system as a straight, self-resonant vertical whose physical height in free space wavelengths is about 1/4 wave.

RF

Oh, then the "electrical length" is the same as "physical length". Why not just say "physical length" then?

> Do you expect your 1/8 WL high, self-resonant helical to have the same
> electrical length and feedpoint parameters as a self-resonant,

You just said that the height of the antenna is the electrical length. So no, I wouldn't expect two antennas of different heights to have the same electrical length, using your definition.

> According to Kraus and other authors, your example above still has
> about the same radiation resistance as a 1/8 WL straight conductor --

It'll be a little higher than a straight 1/8 wave conductor due to a bit more favorable current distribution (see the article referenced in my next paragraph for some actual measurements). But it'll surely not be as high as that of a quarter wavelength conductor. Which of course is the reason it's so important to minimize loss if you want good efficiency.

> An 1/8 WL high helical may be resonant, but it will not perform the

Depends. If the ground system is very good and you're willing to keep to a narrow bandwidth without retuning, you wouldn't be able to tell any practical difference between the two. For good experimental evidence see "The W2FMI Ground-Mounted Short Vertical" by Jerry Sevick, W2FMI in March 1973 QST.

Unfortunately, I understand completely.

Laser = "laser - an acronym for light amplification by stimulated emission of radiation"

Laser rework natural light (radiation).

Antennas produce artifical radiation in the result of the electron oscillations.

To make the oscillations we use different devices.
LC for radio waves, megatrons for microwaves, claystrons for radar waves and the Halbach array for the light frequency.

The word "laser" is probably common name for the all atificical light sources.

Is there a shortage in the supply of coax ? A ham up the road has been
trying to get some rg8x from The Wireman for a couple of weeks. They are
out and said they should have some in soon.

There was also some mention of shortage of the open wire\twinlead type.

Is it just this place or is there some shortage in the US of coax and antena
wire.
What about the other coax such as the rg8 size ?

No, it is not. From answers.com: "Definition: laser - Any of several devices that emit highly amplified and coherent radiation of one or more discrete frequencies."

From Wikipedia: "Light Amplification by Stimulated Emission of

Radiation (LASER or laser) is a mechanism for emitting electromagnetic radiation, typically light or visible light, via the process of stimulated emission. The emitted laser light is (usually) a spatially coherent, narrow low-divergence beam, that can be manipulated with lenses. In laser technology, 'coherent light' denotes a light source that produces (emits) light of in-step waves of identical frequency, phase,[1] and polarization. The laser's beam of coherent light differentiates it from light sources that emit incoherent light beams, of random phase varying with time and position."

should we even bring up its close cousin, the MASER?  I particularly
like this definition:

"MASER stands for Microwave Amplification by Stimulation Emission of
Radiation. A LASER is a MASER that works with higher frequency photons
in the ultraviolet or visible light spectrum"
from: http://einstein.stanford.edu/content/faqs/maser.html

> should we even bring up its close cousin, the MASER?

According to something I read, the MASER, which was introduced while I was still in high school, was the original idea behind the development of the LASER. Thanks for your reference which says: "Basically, a man-made MASER is a device that sets up a series of atoms or molecules and excites them to generate the chain reaction, or amplification, of photons."

What??? A MASER is an RF devices. When discussing RF, aren't photons just a diversion away from "The Truth According to the Great RF Gurus"? Someone should tell the MASER guys that they are just wasting their time associating their RF devices with atoms and photons when they really should be using fields and waves to explain the MASER phenomena. Good luck on that one. :-)

Ralph Mowery wrote:

> Is there a shortage in the supply of coax ?

Yes, but all is not lost. You need to get the newst Ham in the neighborhood and send him out for a coax stretcher. They come in handy from time to time.

I have to admit I never found one in my neighborhood - but all the Hams were very helpful and thought they knew who might be able to help me, and sent me off to the person.

Hello Richard:

(I am not quoting with ">" because I get unpredictable results with google :>))

You said: "Please observe the distinction as appeals to 100W or "one second" have no bearing on where you seem to be fixated with quanta and energy."
I could not translate this sentence, (sometimes your writings are complicated for me Richard, try Tarzan style or better yet... try as you were writing to Cheeta! :>)
(I handed the sentence to a friend who lives in England and today said to me that have so many interpretations and did not solve my problem...)

"Why do you compare 80M to green light?"

Well... I like it! photons born from light, green light it is a central zone of visible light spectrum, and 80 m is my favourite ex-novice band...
Look, light has a very rough "texture", light quanta is a very energetic thing, its "granularity" it is high and we easily perceive its quantic nature, 80 m energy instead has a very, very "soft" texture, 10^8 time softer than green light, and we can not measure its "granularity" with our instruments. Think of a 1000 kg car smashing against your car at 100 km/h, now think of a mosquito (10 mg) smashing against your windshield at the same speed.. well if the one green light quantum had the cinetc energy of a 1000 kg thrown against your car, 80 m quantum would have the mosquito energy! It is a really good

example... you should congratulate me for that formidable approach!!
no?, hi hi

Physicists said that we can better perceive energy glanularity at lower temperatures and they say we have classic behaviour when hv << kT, well... at 1 K, kT it is 6000 times bigger than 80 m hv, a very classic oscilator indeed!, at 293 K ambient temperature I think we can not appreciate quantized nature of RF waves!, (at least with my Bird 43) :>)

I have a question too, please tell me (I am very curious): why you take every opportunity to bite (sting?) my friend Cecil, ah? ;>). I read carefully Cecil writings and I do not find flawings in his affirmations; usually he is very precise and scholar on this matters, sometimes he has an occasional forgivable habit, such his predilection for photons and polished glass things, but I think he has not so "distractive", usually I understand wiich is "his point" to bring another physics areas on the table... I think often we have a little stubborn too :>D

73, and thank you very much for your company - Miguel - LU6ETJ

You should add: "Basically, a man-made MASER is a device that sets up a series of atoms or molecules and
excites them to generate the chain reaction, or amplification, of
photons."

Laser and maser reworks the light produced by atoms or molecules.

In the Halbach array no atoms or molecules.
There are working only the electrons in vacuum. Like in transmitters,
megatrons and claystrons.

Hi Miguel,

Fair enough - and sorry for the density of style.

>(I handed the sentence to a friend who lives in England and today said
>to me that have so many interpretations and did not solve my
>problem...)

Well, that sentence was more about context than it was about style. I am glad you did not ask your friend to read the thread.

>"Why do you compare 80M to green light?"
>
>Well... I like it! photons born from light, green light it is a
>central zone of visible light spectrum, and 80 m is my favourite ex-
>novice band...

Yes, green (actually green-yellow) light corresponds to photopic (day) vision. Scotopic (moonless night) vision is blue-shifted. Sitting inside would tend towards a combination called mesopic vision.

The analogue of the eye as "receiver" gives us the peculiar action of resonance shifting due to strength of the QSO. Propagation fading would find the contact drifting from the 80M Band up through the 60M band.

>Look, light has a very rough "texture",

Is Cheeta trying to say photons?

>light quanta is a very
>energetic thing, its "granularity" it is high and we easily perceive
>its quantic nature,

The eye can sense one photon out of two under the best of conditions, but what that means as far as "granularity" is lost on me. A RADAR (even if not an 80M one) can respond to a pulse it sends and senses in an echo. The packet contains at least 100 to 10000 cycles. Pulse shape signatures would suggest that individual cycles are resolved - granularity?

>80 m energy instead has a very, very "soft"
>texture, 10^8 time softer than green light, and we can not measure its
>"granularity" with our instruments.

The granularity can be expressed in microKelvins of temperature which can be (and has been) resolved. What you describe as "we can not measure" is more a function of background noise, not ability, nor instrumentation incapacity.

>Think of a 1000 kg car smashing
>against your car at 100 km/h, now think of a mosquito (10 mg) smashing

>example... you should congratulate me for that formidable approach!!
>no?, hi hi

Analogies, as we have mulled them over in the past, often lead to their own failure and that, in turn, brings down the central point trying to be argued.

Case in point with your mosquito: The two collision events can also be expressed as energy translation into temperature change. This is called phononic energy - or sound. The crash of cars or bugs resolves into a sound. Do we hear, or do we have the capacity to hear either? Both? There are 8 orders of magnitude difference between the two masses at the same velocities. Our hearing dynamic range easily encompasses that. I can hear bugs bump against my living room window at far slower velocity. I would not hear them with the background noise of an operating automobile and the various road, wind, conversational or radio noises raising the noise floor.

This points out that measurement failures are often a matter of method, hence the human component of psychological impairment. Science is more fascinating in its stories of overcoming shortfalls of perception. Einstein wasn't known for his math, or his benchwork, he gave us perspective.

>Physicists said that we can better perceive energy glanularity at
>lower temperatures and they say we have classic behaviour when hv <<
>kT, well... at 1 K, kT it is 6000 times bigger than 80 m hv, a very
>classic oscilator indeed!, at 293 K ambient temperature I think we can
>not appreciate quantized nature of RF waves!, (at least with my Bird
>43) :>)

All the matter of background noise.

>I have a question too, please tell me (I am very curious): why you
>take every opportunity to bite (sting?) my friend Cecil, ah? ;>).

Probably because you enjoy reading it, otherwise why are you offering
another opportunity? ;-)

Hi hi, no, not Cheeta... Resnick & Halliday & Krane use "granularity"
metaphor, "granularity" and "texture" are words that denote same idea:
ligth photons are really very big Jerry Lee's "Great balls of fire",
80 m photons are very very tiny balls :>) For that reason your eyes
catch light photon, they (photons) are fat guys, you know?.
Glanularity is not about "cycles" but quantum energy =3D> hv,
v=3Dfrequency, high frequency =3D> high energy quantum =3D> high
granularity, not cycles

Not "analogies", no, no, I am only comparing energy magnitud
differences! (I am not resigning my rights to analogies, with this),
10^8 more bigger cinetic E represents so much energy difference at any
scale; obviously a light photon has very, very much lower energy as a
1 t (Tm) car at 100 km/h (it has 3.6*10^-19 J) but 80 m photon it is
100000000 lower!, Can you hear 80 dB sounds below mosquito buzzing?
are you the six million dollar man? :>)
You talk about "fluctuations" OK, can you assure to me those
fluctuations are due quantized nature of RF signals? have you
references about that? Naturally I have my doubts, what you say do not
match my sacred Wiley & sons bible physics verses: remember at only 1
K, kt >> hv, and for R, H & K elders, granularity can not be
perceived.

Well, but stop here, please: I did not say we can not measure 100 W
oscillator granularity, eh?, I am not any authority to say such
thing!, look what the fathers of my church say in page 483:
"Quantized energy simply not reveales in large scale oscillators, the
smallness of the h Plank component make the granulosity very fine
(thin?) so that we can not detect it"
I bet you live a little more near them than I, Ask to them why they
said that. I am innocent, I am only the postman who brings the news
(where is Petrocelli?) :D :D

73 - Miguel - LU6ETJ

PS: Cecil, friend, this man this is already yours. Just confessed his
inconditional love for RF quanta...

I ran in to the same thing last August at the Huntsville, Al. hamfest-
no 450 ohm open wire line.  The high cost of copper prohibits them
from keeping too much inventory on hand.  Apparently not much has
changed since August.

Mmmm, that is at least the second time with glanularity that I cannot
allow to pass:
     Ovarian waves? Cyclic period? Menstraphotons?
well, enough English....

Is a car crash 80dB down from mosquitos? You have your magnitudes
inverted or you are crossing between metaphors (another failure
mechanism).

>You talk about "fluctuations" OK, can you assure to me those

It isn't their field, but that doesn't mean science is invalid. Google
the terms (you already have one in quotes). This has been around for
a decade or more.

>"Quantized energy simply not reveales in large scale oscillators, the
>smallness of the h Plank component make the granulosity very fine
>(thin?) so that we can not detect it"

The problem with selective quoting is that the reader doesn't know the
boundaries - aside from it being a paraphrase and not a literal quote
- unless they write like Cheeta. Sorry for the allusion to a monkey,
but the grammar reveals this is not a true source. I can read between
the lines, but then I get to expand upon that to introduce my own
spin. That doesn't get things very far, does it? Don't pick up on
Cecil's bad habit of leaning on the Xerox copy button.

>I bet you live a little more near them than I, Ask to them why they
>said that. I am innocent, I am only the postman who brings the news
>(where is Petrocelli?) :D :D

Why don't I? The price of email is the same from any location on
earth (or through a satellite link freely accessible from outerspace).

But, when the coax is stretched, what happens to the characteristic
impedance and the loss? [This is a (sort of) serious question!]

Somewhere back in time the word "aperature" was used to describe
antennas, especially stacked arrays. I think one of the prominate
authors that used the expression was Bill Orr.

Would that be relevant to this discussion? I have not heard the term
used in years.

of course they do constant electric field and constant magnetic fields
work just fine and go out to infinity in the dc steady state case.
this of course means there can be no moving electrons, therefor no
current, no d/dt terms, etc... which means no waves.

very fundamental, and very restricted. only good for one point in
space at one time, and for one pair of voltage and current
measurements... can not be applied to separate waves that are
superimposed, only to the final total voltage and current at the
measurement point at that instant.

when doing conservation of energy you must include the WHOLE system!
it doesn't work on one section of a transmission line any more than it
works for the infamous undergraduate teaser:

take a refrigerator, put it in a perfectly insulated room, and then
open the doors... what happens to the temperature in the room?

that site is rather worthless... you say Vs can be used to get the
time reference for the other signals, but time is a variable, as is
space. you seem to have a snapshot of a bunch of sine waves on an
angular scale, but is that scale time or distance?

There again, a non-sequitor non-answer.

Do you reject  P(t)=3DV(t)*I(t) ?

> > Are you saying that conservation of energy only applies some of

I agree completely. And my analysis does successfully track all the
energy at all times.

And after averaging, it even agrees with your analysis.

Methinks that you are perturbed that it demonstrates that your
analysis
does not track all the energy all the time, but only succeeds with
averages.

True, but others reject it completely.

The teaser is amusing, but hardly relevant. In my example, all of
the energy is tracked. Or, I invite you to point out that which was
overlooked. Cecil has not found any and would rather prattle on about
the difference between energy and power than actually understand.

Time, of course. I agree, though, it is not as clear as it could
have been. It helps a bit if you look at Cecil=92s schematic.

Still, it is complicated and will probably take some effort to
understand.

It would probably be better to start with the step wave example
offered previously in another post and copied below for
convenience:

<example>
I am not sure where you think there is an error. Perhaps you can
point them out in the following example:
Generator:
- 100V step in to an open circuit
- 50 ohm source impedance
Line:
- 50 ohm
- open circuit
Generator is commanded to produce a step.
This will produce 50 V and 1 A at the line input which will
propagate down the line.
The open end of the line has a reflection co-efficient of 1.0.
Just before the 50 V step reaches the end of the line, the
whole line will be at 50 V and 1 A will be flowing everywhere.
The 50 V step hits the end and is reflected, producing a 50 V
step (on top of the 50V already there) which propagates back

to the generator. In front of the 50 V step, the current is
still 1 A (which provides the charge necessary to produce
the reverse propagating 50 V step. Behind the step, the
current is 0.
When the reverse 50 V step (which is actually a step from
50V to 100V) reaches the generator, the source impedance
matches the line impedance so there is no further reflection.
The line state is now 100V and 0A all along its length.
The settling time was one round-trip.
The generator is still producing the step, so the forward
step voltage wave is still 'flowing' and being reflected so
there is still a reflected step voltage wave, each of 50 V.
Since the generator open circuit voltage is 100 V and the
line voltage is now 100 V, current is no longer flowing
from the generator to the line.
Does this agree with your understanding?
</example>

...Keith

this is different than what you claimed before. on june 17th you
claimed:
  If(t) =3D 50/50 =3D 1a
  Ir(t) =3D 50/50 =3D 1a

now you sy current is no longer flowing.

i will object to you saying the voltage 'wave' is still flowing. The
line is at a constant 100v, there is no current, there can be no em
wave without current AND voltage, therefore voltage can not be
flowing.

On Jun 28, 5:27=A0pm, Keith Dysart <keith.dys...@gmail.com> wrote:
> And yet, you have not located any errors in the math or the models.

Superposition of power *IS* an error! You add and subtract powers willy-nilly as if that mathematical step were valid which it is not. Two coherent 50w waves do not add up to a 100w wave, even using average powers, except for the special case of zero interference where the waves are 90 degrees out of phase with each other.

In order to use power as an energy tracking tool, we must be very careful to ensure that there is a one-to-one correspondence between energy and power, i.e. every joule passing a point in one second must result in one watt of power (no VARs allowed). If that one-to-one correspondence doesn't exist, no valid conclusion can be drawn from tracking the power and any valid conclusion must be based on tracking the energy which is no small task. The key is that there is no such thing as imaginary energy. All energy is real. Some "power" is not real.

A one-to-one correspondence does not exist in a standing wave. Therefore, tracking power as if it were equivalent to energy in standing waves is invalid. You have made that error for years.

One-to-one correspondence also does not exist over a fraction of a wave. Therefore, instantaneous power is irrevelent in tracking the energy. That's your latest error which is the same conceptual error as before. In general, average power in the traveling waves over at least one complete cycle (or over many cycles) has a one-to-one correspondence to the average energy in the traveling waves. But that one-to-one correspondence is more often than not violated within a fraction of each cycle.

Here's a quote from "Optics", by Hecht, concerning power density (irradiance).

"If however, the 'T' is now divided out, a highly practical quantity results, one that corresponds to the average energy per unit area per unit time, namely 'I'." - where 'I' is the irradiance (*AVERAGE* power density).

If I calculate the Z0 of a 1/4WL transformer, I get two roots when I take the square root of R1*R2. One of the roots is negative. If I ask you to prove something is in error with the math that yielded a negative Z0, could you find the math error? If not, does it follow that you can find the transmission line with the negative characteristic impedance existing in reality?

That's your argument in a nutshell. There may (or may not) be an error in your math but it doesn't matter either way. The conclusions that you reach from your math do not match reality so your math is a moot point, i.e. there is no one-to-one correspondence between your math and the real world.

If you have forgotten the importance of the one-to-one correspondence concept in mathematics, now would be a good time to review that concept. Without a one-to-one correspondence to reality, math is just

fantasy existing only in your mind.

I certainly reject as a moronic method for attempting to track
instantaneous energy.

> I agree completely. And my analysis does successfully track all the
> energy at all times.

That is obviously false. You have tracked the *power* after assuming a one-to-one correspondence between power (watts) and energy (joules). Your assumption is most likely false. You usually cannot use instantaneous watts to track joules within a fraction of a cycle. If the voltage and current are out of phase, some of the joules are occupied as reactive power, and not available as watts of real power. Why do you think the power companies spend so much money trying to balance the power factor?

> Methinks that you are perturbed that it demonstrates that your
> analysis does not track all the energy all the time, but only
> succeeds with averages.

What bothers me is that, "Figures don't lie, but liers figure." :-) I have made no assertion or effort to track instantaneous energy. I would have to review a lot of physics to even remember how. What I do know is that you have been tracking power, not energy, and therefore any conclusion that you reach is probably invalid. You first must prove a one-to-one correspondence at all delta-t sections between the joules at that point and the watts at that point. We know that integrating over a complete second will make the joules equal to the watts for a traveling wave (but not for a standing wave). Now you must integrate over every partial cycle to prove that there are the exact number of joules in that delta-t of time to support the exact number of watts in that delta-t of time. I remember being warned by my professors more than half a century ago that it was a "fool's errand".

> Cecil has not found any and would rather prattle on about
> the difference between energy and power than actually understand.

I have listed a number of the laws of physics that you are violating. Of course, energy and power are different. Consider an ideal LC oscillator at the instant of time when the voltage on the capacitor is maximum and the current is zero. The energy is certainly not zero and can be calculated knowing the voltage and capacitance (assume 1000 volts and 1uf). Yet the instantaneous power is zero because the instantaneous current is zero.

energy =3D (V^2*C)/2 =3D 0.5 joule

power =3D V(t)*I(t) =3D 0

Please prove a one-to-one correspondence between energy and power. How can you possibly say that you are tracking all the energy when the power equals zero and the energy does not? Good grief!

> I am not sure where you think there is an error.

Again, you need to cut off your output and enable your inputs. There are no waves during DC steady-state. Therefore, there are no forward waves and no reflected waves. Therefore, you basic assumptions are invalid. For waves to exist there must be acceleration and deceleration of carrier electrons and such does not exist during DC steady-state. Why don't you know that?

deceleration of carrier electrons and such does not exist during DC steady-state. Why don't you know that?

Why don't you know that oscillating current goes into the displacement current. In EM no reflections.

You should decide: EM or electrons. The mixture is fun.

That's an interesting idea to which I don't know the answer. Let me rephrase the question:

Although it is known that electrons cannot flow through the dielectric of an ideal capacitor, how about photons? Can RF photons flow directly through the dielectric layer of a capacitor? If they can, it would explain a lot of things.

photons can flow through a dielectric.. isn't that what EM propagation
is, after all?

Yes, after I posted it, I realized that it was a rhetorical question.

Dear friends, I follow with interest your interesting digressions,
however in various different posts about differents matters, I notice
discussion arises about what is "real" and what is not. IMO that
contributes to the solution goes away from us (I remember making this
comment in a previous post). In this sense respecto to energy I would
like to quote a great physics:

"...there is a certain quantity, which we call energy, that does not
change in the manifold changes which nature undergoes. That is a most
abstract idea, because it is a mathematical principle; it says that
there is a numerical quantity which does not change when something
happens. It is not a description of a mechanism, or anything concrete;
it is just a strange fact that we can calculate some number and when
we finish watching nature go through her tricks and calculate the
number again, it is the same."

"It is important to realize that in physics today, we have no
knowledge of what
energy is. We do not have a picture that energy comes in little blobs
of a definite
amount. It is not that way. However, there are formulas for
calculating some
numerical quantity, and when we add it all together it gives "28"'=97
always the
same number. It is an abstract thing in that it does not tell us the
mechanism or
the reasons for the various formulas."

From: Richard Feynman. "Six easy pieces"

Sorry, I forget to made clear that my comment not reference Cecil
recent post mentioning "real power" in mathematical sense, referencing
complex numbers. :>)

I learnt displacement current inside a condenser it was =3D eo* d(phi E)/
dt no EM radiation inside the condenser to made that current possible,
in any case EM radiation in physical condenser will come out from
condenser to the rest of the universe :>).
I also learnt photons was necessary to explain certain energy
interchange phenomena such as fotoelectric effect or subatomic
particle interactions, wave-particle duality for me means "duality",
not "wave kaput" :>) to account for EM wave well explainable
phenomenom.
As it was taught to me (I am not physicist), quantum nature of a 80 m
wavelenght energy it is useless for calculations and invisible to our
instrument resolution because its immensely large quantic number. Is
it wrong?

>Although it is known that electrons cannot flow through the dielectric of an ideal capacitor, how about photons? Can RF photons flow directly through the dielectric layer of a capacitor? If they can, it would

explain a lot of things.

Photons are in the real light. The natural light is not coherent. It is
emitted in the portions (packets).
Radio waves are emitted continously. Radar waves are in the portions.

Radio waves and the light photons flow directly through the dielectric layer
of a capacitor.

The difference between EM and electrons is in compressibility.
Electrons are compressed in the ends of the open circuit (condenser and
antenna). There the voltage is doubled (at least). Alternate electric field
is created. It is radio wave. The longitudinal electric wave.

In Heaviside EM (hydraulic analogy) incompressible current (real +
displacement) create the magnetic whirl.
The oscillating magnetic whirl is the transverse wave.

Electrons are simple. Heaviside did not understand Maxwell and made a
complete mess.

Then shouldn't we all expect a condensor to be as good a radiator of
EM waves as a dipole?

Any energy that might raise the temperature is accounted for in the
source and load resistors, so I still suggest that no energy sources
```

or sinks have been missed.

I think I detect a bit of a problem originating with definitions.

Start by considering that old stalwart from the text books: the
infinite transmission line. For convenience, the characteristic
impedance is 50 ohms and at the left end is attached a generator
with a 50 ohm source impedance. The transmission line extends
to the right forever, and this time the generator produces a
sinusoid.

Turn on the generator and it starts to produce a sinusoidal wave.
For greater certainty in the description let us say that the
function which describes the wave is:
  V(t) =3D 100 cos(wt)
where w is the ascii excuse for omega, the angular frequency.

Because the line is accepting this signal and transporting it
away from the generator, the voltage distribution on the line
is also a sinusoid, but spatially distributed along the line.

We can visualise this spatially distributed sine wave as
moving along the line and thus we have the term travelling wave.
If we run fast enough along the line we can get to a point
where the signal has not yet arrived and the line is at 0V,
and if we wait, the sine wave will eventually arrive and
we will observe the same sinusoidal spatially distributed
voltage pattern moving along the line.

We can run the experiment with the generator producing other
functions of time and we would observe the same function
spatially distributed along the line and moving.

A generator producing a square wave will produce a square
wave voltage distribution moving along the line.

A generator producing pulses will result in pulses moving along the line.

A voice signal will result in a complicated voltage pattern moving along the line.

This holds for any wave, V(t), produced by the generator.

But most lines are not infinite. What happens when the line is terminated? Most texts will explain that if a section of line is terminated in its characteristic impedance, that section will behave as if it was connected to a line that continued forever. That is, the observations on that section will be no different than if the line went on and on and on.

Thus in that section we would observe the moving sine, square, pulse, or whatever wave, but, we can no longer run far down the line to find a place where the wave has not yet arrived, since the line has been truncated.

Now what happens if our section of line is open-circuited? The wave reflection model allows us to compute that the reflection coefficient (rc) will be 1. This means that if a forward travelling voltage wave, Vf(t), encounters the open circuit, it will be reflected as a reverse wave, Vr(t).

Mathematically
  Vr(t) =3D rc * Vf(t)

Going back to our waveforms, this is most readily visualised with pulses where the repetition rate is low enough that only one pulse is on the line at a time. The pulse can be seen to travel down the line, hit the end and travel in the reverse direction back to the generator. What happens when the pulse gets back to the generator? Well the generator was specified to have a source impedance that was the same as the line characteristic impedance, so the behaviour on the section of line will be exactly the same as if the line continued forever. There is no reflection, and we can forget about the pulse.

The wave reflection model also tells us that the voltage at any point on the line will be
  V(t) =3D Vf(t) + Vr(t)
where Vf(t) is the voltage from the forward wave at that point on the line and Vr(t) is the voltage from the reverse wave at that point on the line.

For pulses, where there is only one pulse on the line at a time, this is easy to visualise, but for continuous signals, the voltage distribution on the line is now the sum of the forward and reverse travelling waves and for the most part, the forward and reverse travelling waves are no longer easily visible. For example, with a sine wave, the resulting voltage distribution on the line is the time varying, so called, standing wave.

It is important to note that even though the original travelling waves are no longer visible in the spatial distribution of the voltage on the line, the travelling wave continues to be provided by the generator, it travels to the end of the line where it is reflected and this reverse wave travels back to the generator where it behaves as if the line continued forever because the line is terminated by its characteristic impedance.

Recall that all of this holds for any Vf(t) produced by the generator. So what happens with that original sticking point, the step function?

Consider the infinite line again. The step is moving along the line. If we run far enough ahead, we can watch the step pass, but behind the step the voltage is constant. This makes it hard to visualise as a moving wave because there are no peaks and valleys to observe, but it is still moving. If in doubt, just run further down the line to observe the step pass again.

Now if we terminate the line, we can no longer run on ahead to find the step, but the wave is still moving; we just can=92t see it because of the constant nature of the wave after the step.

With the open circuited line, the step function is reflected and travels as a reverse wave back to the generator. Once the step reaches the generator, just as happens for any other V(t) wave, the wave continues to move; it just is not visible. And the voltage at any point on the line can be correctly computed from

  V(t) =3D Vf(t) + Vr(t)

Another way to think of this is to produce the step wave in a different manner. Start with a pulse wave. Then increase the pulse width until it approaches the pulse period. The variation in voltage can still be observed on the line. Then slowly increase the width until it is equal to the period. There is now no longer any variation in the wave to be observed, but the wave is still moving just as it was when the width was infinitesimally shorter than the period.

Another view is to start with a square wave, then increase the period until it is much longer than the duration of the experiment. Over the duration of the experiment, no change in voltage will be observed, but it is a square wave. One could perform a Fourier transform on the square wave, treat all the constituent sine waves as travelling waves, work out the reflections for each, and sum them back. Exactly the same results will be obtained as will be for treating the step as a moving wave, even though there are no peaks and valleys to aid the visualisation.

So I hope that I have persuaded you that it is completely valid to view a step function as a wave that continues to move (though it is hard to see) even after the step has passed.

If not, re-read the above to locate the flaw in my argument.

If you have been convinced, then we can get back to
If(t) =3D 50/50 =3D 1a
Ir(t) =3D 50/50 =3D 1a

Consider a generator, 50 ohms, that produces a 50 V step in to 50 ohms. For this
Vf(t) =3D 50V
The line has a 50 ohm impedance, so
If(t) =3D 50/50 =3D 1A

This is the voltage and current that would be observed on the infinite or terminated line after the step passes.

With the open circuit line, where the reflection coefficient is 1, the voltage will be reflected so that
Vr(t) =3D 50V
after the reverse step passes and
Ir(t) =3D 50/50 =3D 1A

Recalling that at any point on the line
V(t) =3D Vf(t) + Vr(t)
and
I(t) =3D If(t) =96 Ir(t)

we have, after the reverse step has returned to the generator, everywhere on the line:
V(t) =3D 50 + 50 =3D 100V
I(t) =3D 1 =96 1 =3D 0A

This is exactly as expected for a generator with
an open circuit voltage of 100V and an open circuit
line that has no current flowing.

So the wave reflection model, with continuously
forward and reverse waves, accurately describes
the resulting observations on the line, even for
a step wave.

...Keith

You have really latched on to that haven't you. I remember the good ol' days when you were superposing powers and the very same people with whom you are arguing today were trying to convince you that superposing power was an invalid operation.

Now you have bought in to the rule and apply it even where it does not apply.

Just because a sum is being computed does not mean that superposition is at work.

When you add up the energies to validate that energy is not created or destroyed, you are not superposing energy.

When I add up the energy flows for the same purpose, that does not mean that superposition is at work.

From a basic calculus, if the energy balances, so must the energy flow:

f(t), g(t), etc. are functions that describes the energy in individual entities of a system with respect to time. Then

   f(t) + g(t) + h(t) =3D k

is the expression that says the sum of all the energies must be a constant, for energy is neither created nor destroyed.

From basic calculus

   d(f(t) + g(t) + h(t))/dt =3D d(k)/dt
   d(f(t) + g(t) + h(t))/dt =3D 0
   d(f(t))/dt + d(g(t))/dt + d(h(t))/dt =3D 0

d(f(t))/dt is the derivitive with respect to time of the energy (i.e. energy flow, or power) for the entity.

So it is completely valid to sum these energy flows to track the energy within the system; as my example does.

> You add and subtract powers

> Two coherent 50w waves do not add up to a 100w wave, even using
> average powers, except for the special case of zero interference where
> the waves are 90 degrees out of phase with each other.

True. You must always use the actual energy flows in the entity and
not the powers that are not real.

> In order to use power as an energy tracking tool, we must be very
> careful to ensure that there is a one-to-one correspondence between

Also true. And as is done in my example.

> If that one-to-one
> correspondence doesn't exist, no valid conclusion can be drawn from
> tracking the power and any valid conclusion must be based on tracking
> the energy which is no small task. The key is that there is no such
> thing as imaginary energy. All energy is real. Some "power" is not
> real.

Agreed. Especially the power in the waves that are being superposed.
That is why you need a fudge factor when you sum your partial powers
from your waves. I carefully do not sum partial powers from
superposed waves.

> A one-to-one correspondence does not exist in a standing wave.
> Therefore, tracking power as if it were equivalent to energy in
> standing waves is invalid. You have made that error for years.

Please provide an example of such an error, preferably from one
of my expositions.

> One-to-one correspondence also does not exist over a fraction of a
> wave.

Of course it does. Energy must always balance; not just at the end
of the cycle.

> Therefore, instantaneous power is irrevelent in tracking the
> energy. That's your latest error which is the same conceptual error as
> before. In general, average power in the traveling waves over at least
> one complete cycle (or over many cycles) has a one-to-one
> correspondence to the average energy in the traveling waves. But that
> one-to-one correspondence is more often than not violated within a
> fraction of each cycle.

Now you are allowing us to create and destroy energy as long as it
balances at the end of the cycle? Are you sure you want to do this?
It does not align with the well understood principle of conservation
of energy.

If I follow that rule, I just make the cycle long enough, say, my lifetime, and I am golden.

But I do not hold out any hope for this.

> Here's a quote from "Optics", by Hecht, concerning power density

> density).

There you go again, assuming that the 'practical' challenges of optics also apply to transmission lines. On a transmission line, we can measure the voltage and the current. We do not suffer from the same constraints as optics.

Use the tools that are available for transmission lines. Don't tie two hands behind your back just because those tools do not work in the optical domain.

Of course you can. It is just like water flowing from multiple pipes
in to a tank. The sum of the instantaneous flows is exactly equal
to the rate at which the volume of water is increasing in the tank.

Not hard at all.

> If
> the voltage and current are out of phase, some of the joules are
> occupied as reactive power, and not available as watts of real power.

Mostly true. But this is accurately accounted for by using the
instantaneous voltage and current and not the RMS. This is an
important difference expressed in

  P(t) =3D V(t) * I(t)

and why I do not use

  Pavg =3D Vrms * Irms

which has all the problems you mention.
```

> Why do you think the power companies spend so much money trying to
> balance the power factor?

Not for this reason. The energy meter at my house accurately measures the power (using P(t) =3D V(t) * I(t)) and integrates so that they bill me for the energy I have used. And so they do.

Poor power factor does not affect this, but increases the losses experienced by the power company when delivering the energy to me. They want the customer to pay for these losses so they monitor VAR.

Indeed. Power and energy are related in that power is the derivitive
with
respect to time of energy. They are very closely related. See my
other
post for the derivation.

> Please prove a one-to-one correspondence between energy and power. How
> can you possibly say that you are tracking all the energy when the

'cause that is how calculus works!? If one tracks all the flows, then
one knows where the energy is because it can only move by flowing.
Think water pipes and tanks for an analogy.

You, yourself, explained once how you would use the Fourier transform
to analyze such an example. After you have transformed the signal

to the frequency domain, there are enough sinusoidal waves to
keep anyone happy.

Or are you saying that a step function does not have a Fourier
transform?

> I learnt displacement current inside a condenser it was =3D eo* d(phi E)/

> dt no EM radiation inside the condenser to made that current possible, in any case EM radiation in physical condenser will come out from condenser to the rest of the universe :>).

It depends on your definition of "radiation". In an ideal transmission line, energy is not lost to radiation but photons (EM fields and waves) necessarily exist all up and down the line. In an ideal coaxial transmission line, the photons (EM fields and waves) are confined to the dielectric. Electrons cannot travel at the speed of light. EM waves travel at the speed of light. Therefore EM waves are photons. Given the physical nature of a capacitor, refraction would be the primary mechanism for losing energy to radiation and there's probably very, very little refraction in the capacitor dielectric. If electrons are being acelerated and decelerated in the capacitor, photons will be emitted. It seems obvious now that when electrons are decelerated on one capacitor plate, photons are emitted that propogate across the capacitor dielectric and are absorbed by electrons on the opposite plate. When the concept of displacement current was invented, nobody knew that RF fields were actually made up of particles (photons) but now we do know. Displacement current seems only to be EM radiation from one capacitor plate to the other.

> As it was taught to me (I am not physicist), quantum nature of a 80 m wavelenght energy it is useless for calculations and invisible to our instrument resolution because its immensely large quantic number. Is it wrong?

The quantized nature of a single RF photon is no longer open to argument and the energy in that single photon can be calculated, (h*f), where h is Planck's constant, 6.626 x 10^-34 J*s. Whether there are any instruments sensitive enough to detect a single 80m photon is a moot point that does not change the nature of RF fields and waves. What is important is that it is impossible to radiate a signal level less than (h*f). If anyone asserts that RF fields and waves can violate the laws of physics regarding photons, that person is wrong and delusional. (Light left over from the time when the universe became transparent is today red-shifted down to RF microwave frequencies and called background radiation.)

Laser light can usually be considered to be coherent light as are
waves generated by an RF transmitter. But of course, nothing is
perfect.

> Radio waves and the light photons flow directly through the dielectric la=
yer
> of a capacitor.

Energy flow, just not as "current".

"Compressed" may be overstating the phenomenon. Have you ever
calculated exactly how far an electron moves at 10 MHz?

> Electrons are simple.
```

Yes, too simple to move at the speed of light.

Somewhere I came across a setup for a simple "itty bitty" radio
telescope a number of years ago. Its purpose is educational. Basically,
it consists of a discarded 18" dish, power supply, and a satellite
signal finder. I happen to have a Channel Master 1004ifd finder, but it
gets its power from the LNB, which apparently gets it from a satellite
rcvr. I have no rcvr. Is there some simple inexpensive 12v dc power
supply (battery pack) that I could use? I would guess that it would need
a connector of some sort to hook to the LNB.

And I remember the good ol' days when you were still messing your diapers. Do you still do that? I probably did try to superpose power back when I was young and foolish but I learned the error of my ways and corrected it.

> When I add up the energy flows for the same purpose, that does not
> mean that superposition is at work.

But you are NOT adding up the energy flows - you are adding up the power. That's superposition of power and is a no-no. Power does not obey any conservation of power principle. The instantaneous maximum charge on a capacitor contains any amount of energy while power equals zero. What is it about that concept that you don't understand?

> True. You must always use the actual energy flows in the entity and
> not the powers that are not real.

What happens when energy =3D 1 joule, and de/dt =3D 0 watts. This happens all the time during an RF cycle so you are not using actual energy flows. You are using power which goes to zero even when maximum energy is still present. There is obviously NOT a one-to-one correspondence between power and energy.

YOU CANNOT USE WATTS TO TRACK ENERGY UNLESS THERE IS A ONE-TO-ONE CORRESPONDENCE BETWEEN WATTS AND JOULES.

> Also true. And as is done in my example.

Actually false, as I have proved above. Please plot the joules, not the watts.

> Please provide an example of such an error, preferably from one of my expositions.

At a current node in a standing wave, you claim there is zero power which is true. You claim that since there is zero power, there is also zero energy which is absolutely false since that is a voltage maximum point and you will fry yourself if you grab it. The energy in the voltage maximum is unrelated to the power being zero - just one more proof that energy does not correspond to power. At the zero power points, there is a maximum of energy in one of the fields which you are ignoring.

> Of course it does. Energy must always balance; not just at the end of the cycle.

Energy must balance but power doesn't have to balance and usually does not balance. Power only balances for special cases. You are using power in the general case as an example so anything you say is invalid.

> Now you are allowing us to create and destroy energy as long as it balances at the end of the cycle?

No, energy cannot be created or destroyed. But power is created and destroyed all the time because there is no conservation of power principle. Your glaring error is that you are using power as if it were energy and it is not. I have given numerous examples. In an LC oscillator, when all of the non-destructable energy is stored in the capacitor, there is ZERO power, i.e. power has been destroyed. Why do you refuse to discuss that fact of physics? 90 degrees later in the cycle, power has been created.

Every time one of your instantaneous power curves crosses the zero axis, power has been destroyed. Every time one of your instantaneous power curves reaches a peak, power has been created.

> We do not suffer from the same constraints as optics.

You suffer from the delusion that power obeys the same laws of physics

that energy does. You willy-nilly interchange power and energy. Until
you admit the error of your ways, there is little that can be done to
alleviate your ignorance.

> Or are you saying that a step function does not have a Fourier
> transform?

Your example has the step function disappearing during steady-state. DC steady-state has no Fourier transform since omega equals zero. A Fourier analysis requires a recurring function of the sum of sinusoids involving integer multiples of omega*time. Your single step does not recur so your conclusions are invalid.

WEll, lucky me. A small amount of Googling got me to <http://www.aoc.nrao.edu/epo/teachers/ittybitty/procedure.html>
I'm not sure our local The Shack has a choke. I may have one. My LNB is different than the one in the pic. It's a Eagle Aspen DTV32+. I'm sure I have a battery clip and 8 battery holder. This might do it. I didn't notice the Rx connector on my CM, but that is where the power goes. I

may be set.

The antenna is electrically a half wave on 10M to 40M, the electrical length of an element is not directly related to it's physical length. That is how they make a "halfwave" in a stick shorter than a physical quarter wave.

The line "full size halfwave on 2/6 meters" indicates that on those two bands the antenna is not loaded, but actually physically a halfwave antenna. The manual indicates that as initially built to dimension, before adjustment, the antenna is centered on 51 MHz on 6M, and 146 MHz on 2M, so my assumption s it is acutally a halfwave on those two freqs.

Check the a0 coefficient in the Fourier transform. This represents
the DC component of the signal. It is perfectly valid for it to be
the only non-zero coefficient.

Without this, how would you deal with a signal such as
  V(t) =3D 10 + 2 cos(3t)

Alternatively, one can use the standard trick for dealing with
non-repetitive waveforms: choose an arbitrary period. 24 hours
would probably be suitable for these examples and transform from
there. Still, you will have zero frequency component to deal
with, but there will be some at higher frequencies (if you
choose your function to make it so).

Warning! Warning! Descent in to scatology.

Learning is good. But now you want to over apply the rules.

> > When I add up the energy flows for the same purpose, that does not
> > mean that superposition is at work.
>
> But you are NOT adding up the energy flows - you are adding up the

Ummm. Energy flow is power. Joules/s!

If it helps, any place I have written 'power', please replace with
'energy flow'.

> That's superposition of power and is a no-no. Power does not
> obey any conservation of power principle.

Try the multiple pipe, water container, water flow example to
understand how flows must also be conserved if matter (or
energy) is not to be created or destroyed.

> The instantaneous maximum
> charge on a capacitor contains any amount of energy while power equals
> zero. What is it about that concept that you don't understand?

Excellent concept. There is no conflict with conserving flows, or
energy
for that matter.

> > True. You must always use the actual energy flows in the entity and

> is still present.

Yes, indeed. That is a fundamental possibility and occurs on
transmission lines with infinite VSWR.

> There is obviously NOT a one-to-one correspondence
> between power and energy.

Correct. Power is the time derivitive of energy. They are related
but definitely not one-to-one.

> YOU CANNOT USE WATTS TO TRACK ENERGY UNLESS THERE IS A ONE-TO-ONE
> CORRESPONDENCE BETWEEN WATTS AND JOULES.

This is quite incorrect. Energy flows must balance, otherwise energy is being created or destroyed to sustain a difference in flow.

> > Also true. And as is done in my example.
>
> Actually false, as I have proved above. Please plot the joules, not the watts.

If it makes you happier, since it is a discrete simulation, you can simply substitute joules per degree wherever there is a curve labeled Watts. You need to scale, of course, between degrees and seconds, but the shape and sums will be identical.

> > Please provide an example of such an error, preferably from one of my expositions.
>
> At a current node in a standing wave, you claim there is zero power which is true.

Excellent. I am glad you have come to accept that.

> You claim that since there is zero power, there is also zero energy

I have never claimed that. In fact, the minima and maxima are where the energy peaks will be found. I have claimed there is no energy flow across (i.e. power) these points.

> which is absolutely false since that is a voltage maximum point and you will fry yourself if you grab it. The energy in the voltage maximum is unrelated to the power being zero

Not quite. It follows from the functions for each. Since power is the derivitive of energy, it should come as no surprise that maximum energy occurs at the point of minimum power. In basic calculus looking for the zero in the derivitive is how you locate the maximum value of the curve.

> - just one more proof that energy does not correspond to power. At the zero power points, there is a maximum of energy in one of the fields which you are ignoring.
>
> > Of course it does. Energy must always balance; not just at the end of the cycle.
>
> Energy must balance but power doesn't have to balance and usually does not balance. Power only balances for special cases. You are using power in the general case as an example so anything you say is invalid.

Unfortunately wrong. Energy flows must balance as well. Otherwise, energy is coming from nowhere to sustain the flow.

> > Now you are allowing us to create and destroy energy as long as it balances at the end of the cycle?
>
> No, energy cannot be created or destroyed. But power is created and destroyed all the time because there is no conservation of power principle. Your glaring error is that you are using power as if it were energy and it is not. I have given numerous examples. In an LC oscillator, when all of the non-destructable energy is stored in the capacitor, there is ZERO power, i.e. power has been destroyed.

Yes, indeed. At that instant, zero energy is flowing from the inductor to the capacitor. But very soon, energy will be flowing from the capacitor to the inductor. The balance is that the energy flowing out of the capacitor is always and exactly equal to the energy flowing in to the inductor. That is the energy flow balance. The only way for this not to be true is for energy to be created or destroyed.

> Why do
> you refuse to discuss that fact of physics? 90 degrees later in the cycle, power has been created.

One way of thinking about it, I suppose. But not too useful.

Instead, think that at every instant, the energy flow between the entities in the experiment must balance.

> Every time one of your instantaneous power curves crosses the zero axis, power has been destroyed. Every time one of your instantaneous power curves reaches a peak, power has been created.

I think you may be confused because you are only looking at the flow in and out of a single entity. This is clearly not conserved. Nor for that matter is the energy within that entity. It is the total energy within the system that is conserved, just as it is the total of the flows of energy between the entities within the system that must be conserved.

Put more strictly: The sum of all the energy flows in to all of the entities within the system must equal the energy flow in to the system.

> > We do not suffer from the same constraints as optics.
>
> You suffer from the delusion that power obeys the same laws of physics that energy does. You willy-nilly interchange power and energy. Until you admit the error of your ways, there is little that can be done to alleviate your ignorance.

An intriguing accusation, but you do need to provide a concrete example of where my analysis has gone wrong.

...Keith

Yes.

We experience 80M activity every day irrespective of it being Newtonian or Quantum. All it reveals is that something with a very, very, very low energy is still quite measurable.

However, you "can" deliberately choose the wrong instrument to measure the energy. That instrument reveals more about the choice-maker than the energy.

For instance, a 1KW 80M energy source presents a near 0 degree absolute temperature. A fever thermometer is not going to register that energy.

Dear Richard:

What I said is what my physics book says, I swear there no creation of mine... :>) (I have not any authority on this matter).
I was thinking in quantic number describing the energy of a typical 100 W 80 m oscillator devolped in one second, representing a quantic number n =3D 4.3 * 10^28; we know our quanta represents the minimun possible energy of a 80 m radiation AND the minimun "delta" Energy possible for a given oscillator, energy difference between (among?) one quanta an two quanta of 80 m radiation is 2.3 * 10^ -27 J, that difference (my physic book say) it is unmeasurable experimentally (this energy leap (skip?, hop?) it is in the order of 10^-8 smaller that green light leap (in reality my book -Resnick Halliday- give a moving dust particle example with quantic number very much lower than my 80 m example yet =3D> n =3D 3 * 10^14, they said "we can not distiguish energy difference among n =3D 3 * 10^14 and n =3D [3 * 10^14] +1")
What it is the ohysical sense of working with magnitudes we can not measure? Nobody (as we know) use (or need) quantum mechanics to deal with (or explain) locomotive movement :>)

Cecil said "electrons can not travel at light speed, photon yes therefore EM waves are photons", well... EM CAN travel at light speed, then photons are EM waves :D :D As I know duality (particles can behave as waves and vice versa) have not dead yet (or he died and I

found out?).
Cecil said: "When the concept of displacement current was invented,
nobody
knew that RF fields were actually made up of particles (photons) but
now we do know". Cecil seem to me as Zarathustra has declared: "=A1Wave
is dead!" :>)

Yes, yes, I know some people bring very strange ideas into the forums,
but I think it is not necessary argue them with exotic others -even if
they are true- because the partner will double the bet and will bring
other even more bizarre yet...! :>)

Well, dont be bothered by my comments, I am joking a little...

73 - Miguel - LU6ETJ

Keith obviously understands the requirements for energy flow, but a casual reader might draw the wrong conclusions. . .

Keith Dysart wrote:
> . . .

> This is quite incorrect. Energy flows must balance, otherwise energy
> is being created or destroyed to sustain a difference in flow.

On the average, yes. But not moment-by-moment. Energy can be stored and retrieved from storage, resulting in unequal energy flow (power) into and out of a point. For a while. This was explicitly stated earlier when discussing a capacitor, but I think it's important to make the distinction here between instantaneous and average requirements. In steady state, the average condition (energy flow balance) must be met each cycle. That is, the total energy into a node over a cycle has to equal the energy out of a node over a cycle.

> . . .

> Unfortunately wrong. Energy flows must balance as well. Otherwise,
> energy is coming from nowhere to sustain the flow.

Ditto.

> . . .

> this not to be true is for energy to be created or destroyed.

Ditto.

> . . .

> Instead, think that at every instant, the energy flow between the
> entities in the experiment must balance.

No, it doesn't, unless I'm misunderstanding the statement. At a given instant, more energy can flow into a component (e.g., a capacitor or inductor) than is flowing out, or vice-versa. But in steady state, whatever flows in during one part of the cycle must flow out during the remainder of the cycle.

Again, only on an average or steady-state cycle-by-cycle basis. Great inequalities can exist for shorter periods.

>. . .

Like Keith, I firmly believe that an instantaneous time-domain analysis is essential in understanding what really happens to the energy in an AC system. Averaging reduces the amount of information you have -- if all you know is the average value of a waveform, you have no way of going back and finding out what the waveform was, out of an infinite number of possibilities. If averaging is to be done, it should be done after you calculate and understand what's going on at each instant, not before you begin the analysis.

But it's also essential to make absolutely clear what conditions must be met every instant, such as p(t) = v(t) * i(t), and which must be met only on the average, such as energy in = energy out.

Photons are very useful in the analysis of transmission lines. They can be brought into the discussion to divert it from taking a path that makes a participant uncomfortable. If unable to answer a question logically, simply toss photons, optics, quantum mechanics, aether, and other confounding factors in, and presto, people will begin arguing about the spurious concepts and forget that you've avoided answering the difficult question. It's called misdirection, a time-honored technique used by politicians and prestidigitators as well as promoters of pseudoscience.

Hi Miguel,

Power? Energy? One second? Choose one to talk about, and perhaps the mystery of numbers might clear up.

>one quanta an two quanta

Quanta? Two Quanta? We are now up to four intermixed terms. Simplify. Choose one thing.

>of 80 m radiation is 2.3 * 10^ -27 J, that
>difference (my physic book say) it is unmeasurable experimentally
>(this energy leap (skip?, hop?) it is in the order of 10^-8 smaller
>that green light leap

True, but immaterial. You are confusing wavelength and quanta (no surprise given the blearing of topic). Compare Green and IR. Is there a correlation on a scale of two that predicts out to a scale of 10^8?   Compare Green and deep IR. Is there a correlation on a scale of ten that predicts out to a scale of 10^8?   Compare Green and the Sub-millimeter band. Is there a correlation on a scale of 100 that predicts out to a scale of 10^8?

> (in reality my book -Resnick Halliday- give a

So a quantum of smaller energy of a dust particle is measureable but 80M transmission is not? Common sense is wheezing in this dust.

OK, so they are talking about the difference in quantum, not energy. Would it surprise you that you cannot even tell the difference between one quanta of green light and two with conventional detecting technology?

>What it is the ohysical sense of working with magnitudes we can not
>measure? Nobody (as we know) use (or need) quantum mechanics to deal

The limitation is called Quatum Efficiency and the human eye is vastly superior (to all but $1,000,000 components) at rougly QE = 50%.

Hi, i have a 2.4 metre solid dish here and was going to use it for TVRO but havn't got round to it as the majority of it is foreign with subtitles and that doesn't impress me all that much. Just wondering how i might be able to utilise this dish in the HAM scenario. I am a "Standard" licence in Australia which entitles me to transmit on most bands excluding 3776 - 3800, 50 - 52 MHz, 420 - 430 MHz, 2300 - 2302 MHz, 3.5 gig, 10gig, and above. Also can't use WARC bands. So it's a bit limited in the higher part of spectrum but just wondering if someone could offer some suggestions on what i could use it for (Except birdbath, fishpond etc lol)

Thanks

Gary

Ok... could you please explain me how i can build an, e.g., electrical half
wave for the 20 meters in a 3 meters stick ??

I repeat, i'm a great newbie on antenna theory and related arguments, so the
question i pose to you now is not ironic but really posted to increase my
knowledge, if is possible.

Thanks in advance also to other people that may contribute to this question.

"Electrical half wave" doesn't have much meaning when applied to an antenna, so there isn't a good answer to your question. There's no way to make a short dipole behave exactly like a half wavelength dipole in all respects. But if you mean you want to make a short antenna resonant (one of the properties of a physically nearly half wavelength dipole), you can make it or an antenna of any physical size or shape resonant by putting an impedance transforming (matching) network at the feedpoint. Presto, a resonant antenna. If you want the same feedpoint resistance at resonance as a physical half wavelength antenna, you can get that too by adjusting the network component values. The pattern of a dipole of any length shorter than a half wavelength will in practice be indistinguishable from that of a half wavelength dipole. What will happen is that you'll have increased loss due to the larger currents and voltages in the shorter antenna and the matching network, the amount depending on the design. And if the losses are kept reasonable, the bandwidth of the shorter antenna will be narrower than the bandwidth of a half wavelength antenna.

Roy Lewallen, W7EL

The short explanation is "reactive loading".

The simplest way to achieve what you're looking for, is to take a three-meter stick, and wind it with a spiral of wire. The wire should be insulated, to prevent adjacent turns from shorting together. You would feed the antenna in the center, just as if it were a full-sized half-wave dipole.

The exact number of turns required (and thus the total length of the wire you'd need) can probably be calculated, but I lack the detailed information to know just what the calcs are. I'm sure that there are examples shown on the Web, and/or in the ARRL Antenna Compendium books. You can see one example of this approach at

http://www.w0ch.net/travel_antenna/travant.htm

There are a bunch of design alternatives, divided roughly into

(1) Wind the wire evenly along the whole length of each half of the shortened dipole.

(2) Run the wire straight along the pole for part of the way from the center to the end, and wind turns over the rest.

The "travel antenna" is of the latter sort - it puts most of the added inductance (the coiled turns) down near the feedpoint. He designed it as a shortened quarter-wave, but you could take two of these and stick them back-to-back and have a shortened half-wave.

If you measure the resonant frequency of this shortened half-wave and find that it resonates at too low a frequency, then you've got too many turns... remove some and run the wire straight along a portion of the pole (or space all of the turns further apart). If it resonates at too high a frequency, you need more turns (more inductance).

The behavior of this sort of shortened dipole will be similar to that of a full-length dipole, with several differences:

- Slightly less directional gain

- Higher electrical losses in the dipole

- Lower radiation resistance

The latter two factors result in a loss of electrical efficiency... more of your transmitter power turns into heat in the antenna itself, and less is radiated.

The feedpoint impedance is likely to be different than a full-sized half-wave, too... it may be lower (due to the lower radiation resistance) or higher (due to the additional loss resistance) or nearly the same (if these two factors cancel out).

The approach I've described uses inductive loading - you add inductance in series with the antenna in order to resonate it. Another approach is capacitive loading - you add additional capacitive coupling at the ends of the antenna. This can be done by adding a circular metal "hat" at each end, or a set of radial wires sticking out at a 90-degree angle.

The MFJ antenna under discussion actually uses both techniques - it has an inductive loading coil, and a "capacity hat" of wire spokes, at each end of the antenna (actually, one per band that it's supposed to tune). The combination of added inductance, and added capacitive loading, creates the necessary resonance on each band.

Considering the steady state...

If we accept the P(t) is the product of instantaneous voltage and current, then there will be some points on any mismatched line where P(t) is always positive. In between those points, P(t) will have positive and negative excursions.

I think that it is a reasonable interpretation that at those points where P(t) is always positive, then there is never at any instant, a flow of energy away from the load, energy is never exchanged during a cycle across those points, it always flows from source to load.

It may be that energy is exhanged during a cycle at the load end of the line, and it may be that energy is exchanged during a cycle at the source end of the line, but if the line is sufficiently long, there will exist points where instantanous power is always positive, and therefore, energy always flows in the load to source direction at those points.

The notion that a reflected wave in general conveys power over the entire path from load to source is not consistent with the above. This notion is emboddied in common language when talking about 'reflected power', but the language belies the actual phenomena.

Owen

Dear Richard:

On examples we usually start with a visible common data, here I made
with a 100 W TX power during one second to gives certain amount of
energy, this amount of energy stored in a system (for example a LC
tank) gives the quantic number of the system. well... Energy it is
Power * Time and n=3DE/h*v, it easy, it is an electrical cuasi identical
example as page 1616 part II Spanih translated Resnick & Halliday
book. if for Resnick & Halliday guys is a good example for me is good
too :>)

I do not confussing wavelengh with quanta!, quantized energy it is
E=3Dnhv and v it is 1/lambda, how do you calculate E without v in such
equation?
I don not believe my translations are too wrong! I wrote what book say
=3D> "they said "we CAN NOT DISTINGUISH energy difference among n =3D 3 *

10^14 and n =3D [3 * 10^14] +1"), (page 1652 op.cit.); where you read: "quantum of smaller energy of a dust particle is measureable"? my text says just the opposite!

You say: "OK, so they are talking about the difference in quantum, not energy" I do not know if I am translating well your sentence... perhaps you refer to my missuse of the latin word quanta (plural) instead "quantum" (singular) (in spanish we usually say "cuanto/cuantos" -not latin-, in english I believe you use latin, sorry by my translating error), but I think not is that.
Quantum in this context is "energy quantum", they are talking about difference of energy, that difference it is not continuos but quantized, and each energy quantum is 2.3 * 10^ -27 J, one quantum, two quantum... n*quantum, n*quantum in the system =3D E (op. cit. page 1615), what is wrong?

I am talking about 80 m technically useles quantum treatment, and you say to me: "The limitation is called Quatum Efficiency and the human eye is vastly superior (to all but $1,000,000 components) at rougly QE =3D 50%."

What sort of human eye we use to see 80 m "light"? :>)

I did not want go out off topic, I claimed quantum mechanics do not help so much to solve TL related problems and give some reasons for that. I am not an expert in quantum physics and I am not going further that my elementary physic book examples. Are they wrong? well... then, I am wrong too :>) PSE do not argue with me, I am innocent of charges, read the references...

73 - Miguel - LU6ETJ

I'd make a small addition, that . . .there is never at any instant a *net* flow of energy away from the load. . .

The problem is that I don't know of any way to keep track of a particular bundle of energy -- it gets mixed together. So you could have energy constantly flowing both ways through a point while maintaining a net flow (power) in one direction and it would look just the same as energy going only one way. Keith's DC thought experiments illustrate these different approaches and some of their logical -- and illogical -- consequences.

Quite some time ago I wrote and made available a little graphic program showing the voltage, current, power, and energy on lines under several conditions. When a complete standing wave exists, there are points of zero voltage and current and hence zero power. For one half the cycle you can see energy moving into those points equally from both directions (obviously being stored at the node), and during the other half, energy is moving out of those points in both directions (being retrieved from storage). One interpretation is that the energy arriving from the left exits to the right, and vice-versa, and that fits neatly into the concept of waves of energy simultaneously moving in both directions. Or you can decide that the energy which came in from the right exits to the right, and in from the left exits to the left. If that's your interpretation, then you conclude that no energy ever crosses the boundary. I think this is the genesis of Cecil's view that energy waves somehow bounce off the standing wave node. Both interpretations fit equally well with the observed net flow of energy but, like Keith's DC thought experiments and Cecil's writings show, take you down quite different paths when trying to divine some concept of what's fundamentally happening.

it would probably be good on the 2300mhz and higher bands.  not sure
about how good on 70cm it might be off hand.  10ghz is very popular
here in the states, it even has its own contest.  you should probably
try to contact some local microwave guys there and see which bands
have the most activity.

Hi Miguel,

POWER. Please observe the distinction as appeals to 100W or "one second" have no bearing on where you seem to be fixated with quanta and energy. Introducing distractions is not very useful. [I can appreciate that you are not the source of the distractions.]

>I do not confussing wavelengh with quanta!, quantized energy it is

Then quanta is a distraction, or wavelength is.

>What sort of human eye we use to see 80 m "light"? :>)

Why do you compare 80M to green light? The more wavelength appropriate scale would be invisible in the 800nM Infra Red or in the 80nM Ultra Violet. Green light's correlative would be in the 55.5M band (tropical SW).

>I did not want go out off topic, I claimed quantum mechanics do not
>help so much to solve TL related problems and give some reasons for
>that.

Indeed, no doubt this [distraction] is attributable to a Texas [distracting] snake in the grass.

Quantum mechanics can give a certain perspective and sense of scale, but [distracting] amateurs shouldn't try that at home or on the Internet.

> I am not an expert in quantum physics and I am not going further
>that my elementary physic book examples. Are they wrong? well... then,
>I am wrong too :>) PSE do not argue with me, I am innocent of charges,
>read the references...

The Cosmic Radiation Background has been measured to about 2.76 K, where the mapping variation (fluctuations of 30 microKelvins) are within the Energy perturbation (contribution) of our Amateur transmissions.

So as to not argue, I firmly agree with you that no one is going to find any utility in any of this. But the debate will rage on heedless.

That reminds me that somewhere in the morass of this thread, I believe I saw an "exchange" about whether it was more proper to think of a TEM line in terms of inductance and capacitance, or in terms of (electric and magnetic) fields. I suppose someone had lost sight of the fact that capacitance is simply a model that relates energy stored in an electric field to the applied voltage, and inductance is simply a model that relates energy stored in a magnetic field to the conducted current. How easy it seems for some to become so invested in a particular viewpoint that they can't see that other viewpoints are equally valid (and often just a different way to say the same thing) -- and may on occasion lead to new insights. Of course, those viewpoints that have little to recommend them don't have to be given a particularly prominent position in our thoughts. Far be it from me to say that 10MHz energy isn't quantized, but since the quanta are far too small for me to measure, I seldom give them much thought.

Cheers,
Tom

Posted-By: auto-faq 3.3.2 beta (PGPMoose V2.0, Perl 5.005)
Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider amending its charter, and permit limited simultaneous crossposting to rec.radio.amateur.moderated and one other unmoderated amateur-radio-related discussion newsgroup. We are currently trying this on a temporary basis (90 days, through early July 2009), and adopt it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

  http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

Laser light can usually be considered to be coherent light

No. People produce the coherent light in :
http://en.wikipedia.org/wiki/File:HalbachArrayFEL.png

>as are
waves generated by an RF transmitter. But of course, nothing is
perfect.

>> Radio waves and the light photons flow directly through the dielectric
>> layer
> of a capacitor.

>Energy flow, just not as "current".

Each waves transports the mass and energy.

>> Electrons are compressed in the ends of the open circuit (condenser and
> antenna).

>"Compressed" may be overstating the phenomenon. Have you ever
calculated exactly how far an electron moves at 10 MHz?

Electro gas behaves like all gases.

>> Electrons are simple.

>Yes, too simple to move at the speed of light.

Air particles move with the speed temperature dependent.
Electrons do the same.

no they don't... those types of transmitters work just fine in
airplanes with no soil available.

loss of electrons maybe, but due to friction with particulates in the
atmosphere.  also partly due to the fair weather electric field:

What does HT mean in "HT radio"

What do the 2 letters stand for?

Obviously the expression describes hand held radios,
but I cannot find an explanation.

thanks,
w.

"Handie-Talkie" (or variations on the spelling thereof).

This was originally a brand-name term for the Galvin (think
"Motorola") SCR536 portable radio, introduced in 1940.  The
```

```
abbreviation "HT" has since been co-opted by hams (and perhaps others)
to refer to almost any hand-held portable UHF/VHF radio.

Motorola offered commercial handheld radios with model numbers of
"HT200" and "HT220" (and certainly others) that were easily modified for
operation in the 2 meter and 450MHz ham bands and were quite popular in
the early 1970s.

Also, CB's used walkie talkies, and Hams used handy talkies.

Or at least that's the way it was explained to me.

Dear Cecil:

I understand you proposition about energy redistribution on reflections and constructive/destructive interference phenomena. It is easy to me understand tridimensional waves examples interfering on a surface, rendering strips of nulls and maximuns. In a TL I also understand interference must render -for example- a destructive composition towar one direction and a constructive towards opposite direction. Full destructive interference in one directions implies full constructive on the opposite one, rendering a unidirectional energy flow towards the constructive direction, and zero flow toward the other. However I can not visualize a simple mechanism to generate such system in a TL. Tridimensional examples are easily because RF or light source can be set very close to each other as in physics traditional ligth examples and render the interference pattern, but in a TL they need be in the same place: I managed to explain my idea? Give me a hand. (It is a pitty newsgroups do not have image capabilities)

I am studying your paper published in World Radio Oct 2005. Have you a demonstration of the equation cited fro "Optics" book =3D> Pfor=3DPi +P2+2[sqrt(P1P2)]cos(theta)?

While Handy-Talky was probably the most used brand name that Galvin used,
Motorola was so popular that they renamed the company to it.

Geoff.

In the airplanes is the "chassis ground". The large metal surface is the
charge source. The surface exchanges charges with the air.

>loss of electrons maybe, but due to friction with particulates in the
atmosphere. also partly due to the fair weather electric field:
http://www.missioninstruments.com/pages/learning/elec_fields.html

In a short period of time the atmospheric conditions are similar.

I am asking for measurement of the netto current in the track
ground-antenna.
The two measurements: before and during transmitting in the same atmospheric
conditions.

"Static electrical charge can build up to high  values".

It take place during transmmiting.
Without grounding do not work.

I simply want to know "the value of the DC current".

Do you know it in your station?

Continuing with experiment 1 and recalling its description:
- a sinusoidal generator that will produce 50W in to 50 ohms
- attach one half wavelength of transmission line
- leave the far end of the transmission line open
- the generator is constructed in the Thevenin style with a
  voltage source and 50 ohm resistor

for greater certainty we can draw a schematic:

```
    +-------\/\/\/\------+
    |       50 ohms      |
  +-+-+                  |
  | V |                  |
  +-+-+ 100Vrms          +---------------------------
    | sinusoid                1/2 wavelength
    +--------------------+---------------------------
```

The result, as before, is 50W =93reflected power=94, 0W supplied by the source and 0W dissipated in the source resistor. This you explain as =93redistribution towards the load by superposition associated with destructive interference=94.

Short the end of the transmission line. Now 100W is dissipated in the source resistor, but there is still 50W of =93reflected power=94. I assume you will suggest there is now =93constructive interference=94.

Replace the generator with one constructed in the Norton style:

```
    +--------------+-----+
    |              |     |
  +-+-+     50 ohms\     |
  | I |            /     |
  +-+-+ 2Arms      \     +---------------------------
    | sinusoid     |          1/2 wavelength
    +--------------+-----+---------------------------
```

Now, as before, there is 50W =93reflected power=94, but the source is supplying 100W and the source resistor is dissipating 100W.

I assume you will claim that there is now =93constructive interference=94 rather than the previous =93destructive interference=94, but the line conditions are the same. How does the =93reflected power=94 know if it should construct or destroy? The phase is the same.

Apply the short at the end of the line. 0W are now dissipated in the source. =93Destructive interference=94? For some reason? The line conditions are the same.

Consider a generator constructed as below:

```
  +-----\/\/\/\-------+
  |     100ohms       |
+-+-+                 |
| V |                 |
+-+-+ 100Vrms         |
  | sinusoid          |
  |    +------------+-+--+
  |    |            |    |
  |  +-+-+   100ohms\    |
  |  | I |          /    |
  |  +-+-+ 1Arms    \    +---------------------------
  |    | sinusoid   |         1/2 wavelength
  +----+------------+----+---------------------------
```

This generator has the interesting property that the power provided by the sources is constant at 100W, regardless of load.

The sources are supplying 100W, the source resistors are dissipating
100W, and the same 50W of =93reflected energy=94 is =93flowing=94 on the li=
ne.

Apply the short. 100W is being dissipated in the source. The line
conditions are the same.

For this generator, the phase of the reflection does not appear to
affect the kind of interference. Hmmm.

Now for each of the above experiments, remove the transmission line
and attach the load directly to the generator output. In all cases
the generator behaviour will be the same regardless of whether the
half-wavelength line is present or not.

So it still seems to me that the accounting is much more dependant
on the generator construction and the load applied to the generator
terminals than it is on the presence of =93reflected power=94 and
constructive or destructive interference.

...Keith

> demonstration of the equation cited fro "Optics" book =3D> Pfor=3DPi
> +P2+2[sqrt(P1P2)]cos(theta)?

This equation is problematic. Firstly, it mixes power with voltage
since
theta is the angle between the voltage waveforms. As K1TTT said, "why
not just do the whole thing with voltages?" This mixing is bad form
and
clearly demonstrates the incompleteness of the power based analysis.

The second is that there are two solutions depending on whether the
positive or negative root is used? Why is one discarded? Is this
numerology at work?

Thirdly, it only produces the correct answer for average energy flows.
If the instantaneous energy flows are examined, the results using
this
equation do not align with observations.

I have given the equations for what happens at an impedance discontinuity in a transmission line. The s-parameter equations are the same equations in a different format. Simply visualize the voltage phasors resulting from reflections-from and transmissions-through the impedance discontinuity. Let's start with voltages instead of power.

source------Z01=3D50 ohms------+------Z02=3D300 ohms--------load

measured Vfor1 =3D 50v, Vref1 =3D 0v
calculated rho1 =3D (300-50)/(300+50) =3D 0.7143

Vfor1*rho1 =3D 35.7v at zero degrees =3D portion of Vfor1 reflected by the impedance discontinuity at '+'.

Vref2*tau2 =3D 35.7v at 180 degrees =3D portion of Vref2 transmitted back through the impedance discontinuity at '+'.

Vref1 =3D Vfor*rho1 + Vref2*tau2 =3D 0, measured Vref1. This is the same as the s-parameter equation (1).

b1 =3D s11*a1 + s12*a2, all phasor math

These are the two voltage components that superpose to zero volts.
Both of those wavefronts are phasors with phase angles referenced to the Vfor1 phase angle.

Now let's look at the power in the component phasor wavefronts.

(Vfor1)^2/Z01 =3D 50^2/50 =3D 50w, power in the Vfor1 forward wave

(Vref1)^2/Z01 =3D 0^2/50 =3D 0w, power in the Vref1 reflected wave

(Vfor1*rho1)^2/Z01 =3D 35.7^2/50 =3D 25.49w

(Vref2*tau2)^2/Z01 =3D 35.7^2/50 =3D 25.49w

Pref1 =3D 25.49w + 25.49w + 2*SQRT(25.49*25.49)cos(180)

The corresponding s-parameter power equation is:

b1^2 =3D (s11*a1 + s12*a2)^2

b1^2 =3D (s11*a1)^2 + (s12*a2)^2 + 2(s11*a1)(s12*a2)

The two wavefronts that cancel toward the source contain energy before they superpose to zero. Where does that energy go? Superposing to zero indicates total destructive interference toward the source. The conservation of energy principle says that energy cannot be destroyed so it must appear as an equal magnitude of constructive interference in the only other direction possible, i.e. toward the load.

The above equations deal only with the destructive interference toward the source. There is a second complimentary set of voltage/energy equations that deal with constructive interference toward the load.

> I am studying your paper published in World Radio Oct 2005. Have you a
> demonstration of the equation cited fro "Optics" book =3D> Pfor=3DPi

That's easy to answer. The Norton equivalent is a current source so currents should be used in the calculations. The phase angles between the two current components are 180 degrees different from the phase angles between the two voltage components. If the interference between voltages is constructive, the interference between currents will be destructive. Hint: the reflected current phasor is 180 degrees out of phase with the reflected voltage phasor because of the direction of travel of the reflected wave. As a result of directional convention, the power in the reflected wave is negative.

So destructive interference for forward/reverse voltages is constructive interference for forward/reverse currents and vice versa. An SWR voltage maximum (constructive voltage interference) is an SWR current minimum (destructive current interference) and an SWR voltage minimum (destructive current interference) is an SWR current maximum (constructive voltage interference).

Oh, I'm so sorry Cecil, I should have written "However I can not
visualize a simple PHYSICAL mechanism/example to generate
such system in a TL". Anyway, your additional info it is very usefu to
me. Thanks.

Miguel

On Jun 24, 5:27=A0am, Keith Dysart <keith.dys...@gmail.com> wrote:

> This equation is problematic. Firstly, it mixes power with voltage
> since theta is the angle between the voltage waveforms.

You apparently don't understand what happens when one takes the dot product of two voltage phasors (and divides by Z0). The result is watts but the math involves the cosine of the angle between the two voltage phasors. All competent EEs should already know that.

> As K1TTT said, "why not just do the whole thing with voltages?"

Because the title of this thread is: "What happens to reflected energy?", not what happens to reflected voltages? Doing the whole thing with voltages allows the obfuscation of interference to be swept under the rug.

Because some of you guys don't recognize interference when it is staring you in face? I was taught to recognize interference between voltage phasors at Texas A&M in the 1950s. What happened to you guys? Here's a short lesson about dot products of voltage phasors and the resulting interference between the two voltages.

Vtot =3D V1*V2

Vtot^2 =3D (V1*V2)^2

Vtot^2/Z0 watts =3D (V1*V2)^2/Z0 watts

There will be the two obvious power terms, V1^2/Z0 and V2^2/Z0, representing the powers in the individual waves before superposition. There will be a third, additional interference term whose dimension is watts that *requires the dot product* between the two phasor voltages. Therefore, your objection is apparently just based on ignorance of the dot product of two voltage phasors.

> This mixing is bad form and
> clearly demonstrates the incompleteness of the power based analysis.

Good grief! This "bad form" has been honored in the field of optical
physics for at least a century. It was taught in EE courses 60 years
ago. I don't know what has happened in the meantime. Walter Maxwell
explains interference in section 4.3 in "Reflections" and obviously
understands the role of interference in the redistribution of energy.

> The second is that there are two solutions depending on whether the
> positive or negative root is used? Why is one discarded? Is this
> numerology at work?

Negative power is just a convention for "negative" direction of energy
flow. All EEs are taught in our engineering courses to ignore the
imiginary root when calculating resistance, energy, or power.

For instance, the Z0 for the 1/4WL matching section between R1 and R2
needs to be SQRT(R1*R2). When you perform that math function, do you
really go on a world-wide search demanding a transmssion line with a
negative Z0? Please get real.

> Thirdly, it only produces the correct answer for average energy flows.
> If the instantaneous energy flows are examined, the results using
> this equation do not align with observations.

You forgot to add that instantaneous energy is as useless as tits on a
boar hog, or as Hecht said, putting it mildly: "of limited utility".
It appears to me that instantaneous energy is just a mathematical
artifact inside a process requiring integration in order to bear any
resemblence to reality. Omit the integration and the process loses
touch with reality. Instantaneous energy has zero area under the curve
until the intergration process has been performed. A zero area
represents zero energy. Otherwise, when you integrate from zero to
infinity, the result would be infinite energy.

Do you have any kind of reference for your treatment of instantaneous
power?

The physical mechanism is the Z01=3D=3D>Z02 impedance discontinuity with
its associated reflection coefficient, rho. We can see that reflection
on a TDR so it is indeed a PHYSICAL mechanism.

Sorry, I lost my train-of-thought here and changed horses in mid-stream. All I was trying to illustrate is that the dot product of two voltage phasors divided by Z0 has the dimensions of watts and contains the cos(A) term. Again, my apology for wandering off the logical path.

Would that be the so-called "fair weather current" about 1 pA/square meter?

Obviously, a big metal tower is going to perturb the local field, so a
tower with a cross section of 1 square meter is going to have a current
a lot bigger than 1pA.

But probably not microamps.

OTOH, a big tower could have substantial capacitance to ground.. I don't
recall off hand what the capacitance of a isolated cylinder is..
I seem to recall that for a rod with length>>diameter, it's something
like 50pF/meter.

So, a 100 m tower will be 5000 pF.

Say the current is 1000 pA.

In one second, the voltage would be 1E-9/5E-9 = 0.2V

In a minute, 30V
In 10 minutes, 300V..

etc

Probably not enough to charge to voltages quickly enough to be a problem.

Tribocharging from dust and other particulates blowing in the wind is a
LOT faster and a bigger problem.

don't forget the OTHER physical mechanism that is necessary,
superposition... the ability to add voltages, currents, and fields in
linear circuits and media.

there is no static build up while transmitting from an antenna
isolated from ground. easily measured and proved here every day.

He has yet to wonder how satellites could transmit very long. After all, there would come a point in time where the charge would be so high on the vacuum insulated satellite that it could perform his field emission any longer.

It should be easy to observe as the signal strength would decrease with time. I haven't noticed that effect myself, nor has anyone else.

Very inventive. And the wave just knows the difference between the
50ohm
generator that is constructed in the Thevenin style and the 50ohm
generator constructed in the Norton style. Amazing waves.

And now the explanation for the mixed constant power mixed Thevenin/
Norton
generator is ...?

...Keith

Still does not explain why you choose only the positive root.
Especially when you let the result be negative as a consequence
of cos(theta).

I always get a chuckle when you write this. It makes me think of a
kid,
who, upon being told that he can not have his favourite dessert until
he finishes his brussel sprouts, declares that he has always hated
that dessert.

You might study why the real power folk prefer three phase to single.
It all has to do with instantaneous power.

Might not make a difference for light, but it sure helps the
understanding at RF and lower.

And your analysis still only produces the correct answers for the
average and still gets the instantaneous wrong. I do see the benefit
of repeating "of limited utility".

As I suggested above, have a look at the benefit of three phase over single.

But then what explains the reflection at the generator that presents
Z0
to the line?

Hello Cecil. I will try another translation because I think I could not explain well my question.
We can see energy maximuns and nulls with simple experiments with light. We set a double slits experiment and we see light flowing in same direction reinforcing and cancellating in maximuns and minimuns on screen. You name it "redistribution", the energy "dissapearing" from nulls reappears on maximuns (Sorry, I use this horrifying light example too because physics books have such unhealthy trend to explain wave interference)
In a TL, instead, total destructive interference in one point would mean energy stop flowing from that point forwards (is it OK say "forwards"?) and reverse its flow direction doubling his value, is it OK?. You name it "redistribution" too, not reflection. Well, my question was how we can set (devise) an experiment to get such behaviour in a TL? We need add (or put) in this point a source of energy to make the interference (the second slit light source from the light example, or the other front wave in a diffraction example), how to, here?. Light experiments is easy because we put both independent coherent light sources near each other illuminating the screen but here I can not visualize how put them. I hope I was explain better my question.

73 Miguel

See; http://en.wikipedia.org/wiki/Ground_(electricity)
" In electronic circuit theory, a "ground" is usually idealized as an infinite source or sink for charge, which can absorb an unlimited amount of current without changing its potential."

"The use of the term ground (or earth) is so common in electrical and electronics applications that circuits in portable electronic devices such as cell phones and media players as well as circuits in vehicles such as ships, aircraft, and spacecraft may be spoken of as having a "ground" connection without any actual connection to the Earth. This is usually a large conductor attached to one side of the power supply (such as the "ground plane" on a printed circuit board) which serves as the common return path for current from many different components in the circuit."

" no static build up while transmitting " because your station has ground.

> vacuum insulated satellite

"The use of the term ground (or earth) is so common in electrical and
electronics applications that circuits in portable electronic devices such
as cell phones and media players as well as circuits in vehicles such as
ships, aircraft, and spacecraft may be spoken of as having a "ground"
connection without any actual connection to the Earth. This is usually a
large conductor attached to one side of the power supply (such as the
"ground plane" on a printed circuit board) which serves as the common return
path for current from many different components in the circuit."

>that it could perform his field emission any longer.

In the vacuum is the rare plasma. The are free charges.

> It should be easy to observe as the signal strength would decrease with
> time. I haven't noticed that effect myself, nor has anyone else.

Are you sure?
Each ground must be large enough. Engineers know what to do.
Sometimes they water the ground area.

In the space the chassis must be large enough.

I mentioned same comment in another post. We use superposition
principle in two different contexts. Superposition theorem in circuit
theory, and wave superposition. Wave (traveling) superposition deals
with f(t,x,y,z) and usually with puntual magnitudes, E, H, D, B, etc)
while circuit theory deals with a subset f(t) phenomena and with
integrated magnitudes (V, I). Sometimes that becomes a confused
issue :)

It is flowing all the time. We are interesting in the transmissing time.

It works in the both directions. Charged tower lose charges.

NO, superposition is always the same.  it is the linear addition of
currents or fields in a linear media.  it works the same for circuits
as for em waves.

the big problem are the people who confuse the formulas for adding
powers with adding fields or currents/voltages and forget the phase
terms.

the other big problem is keith who seems to want to separate his waves
into separate time and space variables and leaves out the requirement
that wave functions must be dependent on both space AND time.
basically any solution to the wave equations derived from maxwell's
laws must be of the form f(t-x/v).  this leads him to the erroneous
```

conclusions he gets from trying to compare his batteries to wave propagation. this is the same problem people have with standing waves, they have separate dependence on t and x, so they can't travel and can't transport energy.

you are almost as much fun as art with his magical levitating
neutrinos.

no, i have antennas that are isolated from ground.  they are fed
through a capacitor that prevents the charge from flowing to ground
and they do not get charged over time.  i know this because when a
thunderstorm is nearby they build up enough charge to arc over the
capacitor.  if there was charge being constantly emitted when they are
transmitting the capacitor would arc all the time.

Repeating myself - it is not necessary for you to imagine magical smart waves. Ignorant people invent magic and metaphysics to explain away their ignorance. All you need to do is to alleviate your ignorance concerning the laws of physics which those ordinary EM waves are obeying. *Externally*, it doesn't matter whether you use voltage superposition, current superposition, or EM field superposition - the results are identical. Every EE professor I ever had warned me about trying to look inside a Thevenin or Norton source at the power dissipation in the source resistor. For instance, their internal dissipations are exactly opposite for shorts and opens so exactly why should you expect the internal interference levels to be the same? When the Thevenin source is dissipating all the power inside the source from being connected to a *short-circuit*, it is experiencing total constructive interference. When the Norton source is dissipating all the power inside the source from being connected to an *open-

circuit*, it is experiencing total constructive interference -
opposite external conditions causing exactly the same phenomenon
inside the two source boxes.

> And now the explanation for the mixed constant power mixed Thevenin/
> Norton generator is ...?

Neither the Thevenin equivalent source nor the Notron equivalent
source is "constant power". The Thevenin equivalent source is a
constant voltage source with a series source resistor and the Norton
equivalent source is a constant current source with a shunt source
resistor. A constant power source is conceivable but it would either
need a circulator plus load, have a pretty sophisticated feedback
system, or be driving an ideal instantaneous antenna tuner.

> Still does not explain why you choose only the positive root.

Of course it does. In the power density equation, choosing the
negative root would lead to a violation of the conservation of energy
principle. When one of the roots is obviously impossible in reality, a
rational person chooses the other root.

> You might study why the real power folk prefer three phase to single.
> It all has to do with instantaneous power.

I am a "real power folk", Keith. My first EE degree was in power
generation and transmission. Three-phase puts less stress on the
system by eliminating the hills and valleys in the energy flow common
with traveling waves. But why do you believe that three-phase power
transmission is relevant to ham radio? Are you running three-phase RF?

Maxwell's equations don't even work for your mashed-potatoes version
of energy. That should tell you something.

> But then what explains the reflection at the generator that presents
> Z0 to the line?

Your error is in assuming it is a reflection. It is NOT a reflection which, by definition, involves one wave. It is a redistribution of energy due to superposition which, by definition, involves two or more waves. In a system designed to eliminate reflections at the source, ALL of the redistribution of reflected energy back toward the load is due to superposition accompanied by interference. From the FSU web site:

"... when two waves of equal amplitude and wavelength that are 180-degrees ... out of phase with each other meet, they are not actually annihilated, ... All of the ... energy present in these waves must somehow be recovered or redistributed in a new direction, according to the law of energy conservation ..."

Nothing said about *reflection* (involving a single wave). It is all about the meeting (superposition) of two waves which can cause the redistribution of energy. It may look somewhat like a reflection but it is technically NOT a reflection.

In our ham transmission line systems, the goal is to accomplish total destructive interference toward the source, i.e. zero reflected energy incident upon the source. So let's talk about destructive interference toward the source and constructive interference toward the load.

> You name it "redistribution" too, not reflection.

By definition, reflection is something that happens to a single wave. By definition, superposition involves two or more waves. The redistribution that I am talking about can include both reflection and superposition if both are present. Depending upon the system configuration, both may be present, both may be absent, or one exist without the other.

> Well, my
> question was how we can set (devise) an experiment to get such

> behaviour in a TL?

I've presented it before and it is a simple Z0-match involving a 1/4WL
matching section.

50w-----50 ohm-----+------1/4WL 300 ohm------1800 ohm load

On the source side, rho at '+' is 0.7143

Using a TDR, we can verify that there is indeed a reflection from the
50/300 ohm impedance discontinuity. What happens to that reflection
during steady-state?

What happens to Vfor1(rho) =3D 50v(0.7143) =3D 35.7v?

What happens to Pfor1(rho^2) =3D 50w(0.51) =3D 25.5w?

No luck this time doesn't mean always bad luck.
I've tried my 6M ECO vertical antenna on 20M with succes. VSWR is ok by
tuning just a bit and on BPKS31 it works outstanding.

Your station produces asymetrical pulses. The all real waves are not
symmetrical. The insulator in the capacitor is a poor conductor but its
surface is large.
It CONDUCTS because the pulses are not symmetrical.

>and they do not get charged over time.

They must: " In electronic circuit theory, a "ground" is usually idealized
as an
 infinite source or sink for charge, which can absorb an unlimited amount of
```

current without changing its potential."

The electronic circuit theory is the ruler in your station. Not EM.

Your capacitor is fit to transmitting not for lightnings.
S*

>> But then what explains the reflection at the generator that presents
> Z0 to the line?

>Your error is in assuming it is a reflection. It is NOT a reflection which, by definition, involves one wave. It is a redistribution of energy due to superposition which, by definition, involves two or more waves. In a system designed to eliminate reflections at the source, ALL of the redistribution of reflected energy back toward the load is due to superposition accompanied by interference. From the FSU web site:

>"... when two waves of equal amplitude and wavelength that are 180-degrees ... out of phase with each other meet, they are not actually annihilated, ... All of the ... energy present in these waves must somehow be recovered or redistributed in a new direction, according to the law of energy conservation ..."

>Nothing said about *reflection* (involving a single wave). It is all about the meeting (superposition) of two waves which can cause the redistribution of energy. It may look somewhat like a reflection but it is technically NOT a reflection.

In the Hertz dipole the reflection take place but in the loop antenna "two waves of equal amplitude and wavelength that are 180-degrees ... out of phase with each other meet,"

But the both cases are the same. At the meeting the energy is radiated and the electrons emitted because in the meeting place the voltage is doubled.

The electronic circuit theory do not use EM.

I did not say that things were fundamentally different, I said
"context" it is different, as "substraction" in mathematics, you can
not subtract a natural number bigger from a smaller one in natural
field, but you can do it in integer field, we have to apply (comply?)
contextual rules with such operations. Otherwise I agree with what you
say. 73

That's the time domain. Variation in the instantaneous energy flow.

Not quite
'as useless as tits on a boar hog, or as Hecht said, putting it
mildly: "of limited utility"'.

Now this I agree with. Superpose volts, current and fields to your
heart's content. Just don't attempt it for power.

You should study the design of the generator described previously and
repeated below, for your convenience:

```
  +-----\/\/\/\-------+
  |     100ohms       |
+-+-+                 |
| V |                 |
+-+-+ 100Vrms         |
  | sinusoid          |
  |    +------------+-+--+
  |    |            |    |
  |  +-+-+   100ohms\    |
  |  | I |          /    |
  |  +-+-+ 1Arms    \    +---------------------------
  |    | sinusoid   |         1/2 wavelength
  +----+------------+----+---------------------------
```

As I said, this generator has the interesting property that the power
provided by the sources is constant at 100W, regardless of load.

Can you make your redistribution explanation work for this one?

> What happens to Vfor1(rho) =3D 50v(0.7143) =3D 35.7v?

Using superposition, when you add Vrev2(tau) to Vfor1(rho) you get zero.
With zero voltage comes 0 energy transfer.

For further learning, do not just examine steady state, but also examine
how it gets to steady state. Using a lattice diagram, examine what happens as the first reflection and then each re-reflection arrives at '+'. Determine how Vrev2(tau) slowly builds to equal Vrev1 and cancels it, using the simple addition of superposition. While this process is occurring, there is a Vrev1 which decreases after each round trip in the second line section.

This is all done with simple addition. No need for products and square roots.

For further marks, decide whether you should think of Vrev2 as an infinite sum of reverse waves or is it okay to think of it as one sum that slowly accumulates.
Which is it really?

Same question for Vfor2.

> What happens to Pfor1(rho^2) =3D 50w(0.51) =3D 25.5w?

Once you have computed total Vrev1 using simple superposition, it is easy to compute that the "reverse power", Prev1, is 0.

Do you really need rho^2 to understand what goes on in a transmission line?

...Keith

Owen, my thinking was to make a transmission line with a characteristic
impedance that gradually changed from 600 ohms down to as close to
200 ohms as practical, just to avoid the impedance bump at the junction
of the open wire and shielded balance line. I've found a few

references that state the taper should follow a log response; and also if the line needs to be a wavelength or longer pretty much dashes that idea. It would be a lot easier to construct a line with charateristic impedance of 400 to 600 ohms, and deal with narrow spacing issue for only a relatively short portion of the entire span.

I didn't expect the shielded cable to be immune to common reradiation problems, but that issue could be dealt with separately if it was a problem. Pete

the ground radiates? that's interesting.

so the raised radials on my 80m 4-square would be considered an rf ground?

I would consider them to be an effective RF ground at their 1/4 wave resonant points, just as would a tuned artificial RF ground used for stations at elevated locations.

Okay, then it might make sense to do this: Plan II

instead of using the balun is in the tuner, there is no reason
why I couldn't mount another 4:1 balun outdoors, and use a short run
of low loss coax back through the conduit into the operating room.

That would be about 15 feet of LMR-400 cable. I could go to 1/2 heliax
but would there be any benefit??

So, I would have balanced open-wire feedline from the dipole to
the 4:1 balun followed by a 1:1 common-mode RF choke with
the requiste RF ground for decoupling,
followed by the short run of low loss coax going back to a
unbalanced ant. port on the tuner. I'd still have coax in the mix,
but the 4:1 balun should hopefully tame the high impedance
excursions across the antenna operating range to
reduce the coax's losses at those points?

Otherwise it is going to be hard to get balanced line into the shack,
unless I pull it through the PVC conduit with the other coax cables.

See my article entitled "Is a 4:1 balun a good choice for use with an ATU on HF?" at http://vk1od.net/blog/?p=987 .

It is difficult to answer the question about the LDF without knowing the impedances involved. I used TLLC (http://www.vk1od.net/calc/tl/tllc.php) to work the examples I gave, you could do the same if you know the feedpoint impedance etc.

If you want to solve the cases for an arbitrary two wire line, try http://www.vk1od.net/calc/tl/twllc.htm .

Thanks, Owen. I made up my test after reading the june 2008 QST
story.

Looks like most of the information I needed was already
written up on the DX Engineering webpages. I'll have to
go do a bit more reading before committing to anything.

Thanks for all the comments so far....

Pete

I should have mentioned that 4:1 baluns integrated into ATUs are most often voltage baluns.

When operated near a voltage maximum with high standing waves, they can be very lossy. Sometimes it is claimed that they 'tame' difficult antennas better than current baluns, which is often due to their internal loss. The problem as such is not the balun, it is the extreme load presented by a very poor antenna, and the lossy balun is a poor (grossly inefficient) circumvention.

So, when a 4:1 voltage balun allows a match where a 1:1 current balun doesn't, the problem is probably the antenna, not the balun.

You might consider the following experiment:

- a sinusoidal generator that will produce 50W in to 50 ohms
- attach one half wavelength of transmission line
- leave the far end of the transmission line open

After the line settles, a directional "wattmeter" anywhere on
the line will indicate 50W forward and 50W reflected.
The generator will not be putting any energy in to the line

since the line input appears as an open circuit at the
generator output.

Insert a circulator (with the reflected port terminated in
50 ohms) between the generator and the line. The circulator
termination will be dissipating 50W and the generator will
now be delivering 50W in to the circulator.

1. Please explain how inserting the circulator did not change
   the circuit conditions. The generator went from delivering
   0W to delivering 50W.

2. Where do you think the 50W being dissipated in the circulator
   termination resistor is coming from? The line? Or the
   generator (which is now outputting 50W)?

Just for fun, you may be interested in a DC coupled circulator
that works all the way down to 0 Hz:
http://www.techlib.com/files/RFDesign3.pdf

Answer question 2 for this circulator design.

That's pretty much what I've been reading on various websites.
At least some of the mystery is being cleared up :) A fan dipole
is starting to look better; at least I can control the feedpoint
impedance to within reason and keep a decent pattern on
the bands.

Gentlemen, I have an idea for a "portable AM radio" antenna to allow the user to hear the station clearly while walking, no matter what direction the radio is held.

Just have three bar antennas, aligned along the X, Y, and Z axes, like http://en.wikipedia.org/wiki/Jacks , or independently placed inside the case. A microchip would constantly pick the best signal from amongst them. Maybe even just two axes would do.

Great for farmers who are walking around all day, and just can't give up their favorite AM station for FM.

It has been done. It's a form of diversity reception. It would require a radio with two separate receivers in it. I think the liklihood of a manufacturer deciding to build a radio optimized for your two applications is kinda slim.

Why not try two small radios and join their outputs?   Mount them corner-to-corner (90-degrees opposed) so that when one is in the null, the other one is at the peak. Couple the hot sides of each of the output jacks together through a pair of small resistors, say 39 ohms. You probably need to know how to solder and know where Radio Shack is for a few small parts.

Next time I'm at the swap meet, I'll see if I can find a matched set of mini-cheapo portable radios and maybe try it myself.

> Reflected waves heat finals, no they
> don't, yes they do, ... but eventually I learned.

Hopefully, you learned that rail arguments are rarely valid and the truth usually lies somewhere in between. Sometimes reflected waves heat finals and sometimes they don't. It all depends on what kind and how much interference exists between the forward wave and reflected wave at the source impedance and (apparently) how much of that impedance is dissipative or non-dissipative. Roy's food-for-thought article doesn't take interference into account at all and therefore arrives at magic conclusions divorced from reality.

> Anyhow, I suggest you read my examples and find the flaws, for that
> is the surest way to convince me that I am wrong.

I have pointed out many of the flaws in your examples. The way you parse the energy violates the laws of physics. Maxwell's equations only work on a function that contains classic EM traveling waves. Standing waves and DC steady-state examples don't meet the necessary boundary conditions. In fact, it can be proved that EM waves do not existent during DC steady-state. The fact that an instrument designed to detect EM waves malfunctions during DC steady-state is not unexpected. Even an SWR meter calibrated for a different Z0 than the one being used will indicate false results.

You really need to learn to recognize when your experiment and your math model are contradictory, when your concepts violate the laws of physics, and when you have chosen the wrong measuring equipment. You remind me of myself when I was 14 years old and tried to measure the

screen voltage on a vacuum tube using a Simpson multimeter. It wasn't
anywhere near the voltage specified in the manual so I wasted my money
by buying a new tube the next time my family made a trip to Houston.

You would report those same measurement results as proof of a strange,
magical happening.

Oh yeah, according to you, the light beams are changing directions at
every voltage and current node. Sorry, I do not accept your
metaphysics, especially when they violate the accepted laws of
physics.

The generator went from experiencing total destructive interference to experiencing zero interference. Of course, the entire purpose of inserting the circulator is to cause the generator to see 50 ohms as a load impedance.

> 2. Where do you think the 50W being dissipated in the circulator
> =A0 =A0termination resistor is coming from? The line? Or the

TV ghosting experiments will verify that the signal being dissipated in the circulator load resistor has made a round trip from the generator to the end of the N(1/2WL) stub and back to the circulator. Please don't insult our intelligence by arguing that is not a steady-state condition.

It is my experience that the null of a ferrite bar antenna is very few
degrees,
making it a little dificult to get a good null.
I have not had a problem with AM.
FM on my mp3 player which uses the headphone cord as the antenna and
is a problem with respect to the direction and terrain around me.

If antenna emits electrons (longitudinal Tesla waves) than the ground is the source of them.

The lovers of the TEM will write more.

Yes..

Tapered transmission lines have been around for decades, and work just like you'd expect.

For the ultimate in performance, you actually want to use an exponential taper (spacing increases by the same percentage per unit distance), but a linear taper (spacing increases by the same distance per unit distance) works pretty much the same, especially if the taper is "long" (>10x) relative to the spacing. that is, going from 1" to 3" spacing over a foot or two..

As an academic exercise, for example using a tapered line to match an OCD with a known FP impedance of 200 ohms down to a 1:1 balun at the 50 ohm coax line transition point. What is the recommended minimum length of cable needed to perform a four to one characteristic impedance change in the open wire for relating to the wavelength?

Pete

What's the VSWR and frequency spec?

50 ohm balanced pair might be hard to come by.. the usual 276*log10(D/d)
equation is only valid when D>>d. (D = spacing, d = diameter) and just
ballparking 50 ohms means that the spacing between the wires is about
10% more than the diameter (D/d <1.1). 200 ohms is more like D/d = 3

Pete,

You really don't disclose very much, certainly not in a clear way. But, some of your hints (eg OCD with open wire feed) leave me asking why? I am not going to waste time writing a lot of words based on a hint though.

Owen

It's not practical to make a 50 ohm open wire line. The wires would have to be extremely close together.

But as to "recommended" minimum length, it depends on who does the recommending and what your criteria are. The length of line necessary to transition from one impedance to another depends on at least three things: the amount of transformation required, the type of taper (e.g., linear, exponential, Klopfenstein), and how close the impedance match has to be (usually specified as input reflection coefficient). There's a brief treatment in Johnson, _Antenna Engineering Handbook_.

In Brown, Sharpe, Hughes, and Post, _Lines, Waves, and Antennas_, it's stated that the tapered section must be at least a quarter wavelength long, and that if less than that, "it will fail in its matching function".

In Skilling, _Electric Transmission Lines_, ". . . a 2 to 1 change of characteristic impedance many be accomplished by using a tapered section that is 1 wavelength long. A good impedance match results at this frequency and at all higher frequencies. Results are fairly good if the tapered section is as little as 1/2 wavelength long, particularly if the impedance ratio required is less than 2 to 1. It is not worth while to use a tapered section much shorter than 1/2 wavelength, for a taper that is 1/4 wavelength or shorter will give nearly as much reflection as will the abrupt change of impedance at a mismatch. Those frequencies for which the length of the taper is a multiple of a half-wavelength are transmitted with the least reflection. This may be a guide in choosing the length of the taper." The author goes on to state that linear and exponential tapers give practically the same results, and summarizes with a recommendation that a tapered section be between 1/2 and 1 wavelength long at the lowest frequency of use.

Roy Lewallen, W7EL

well, its coming from the generator via the far end of the line of
course.

the result is no current, but 50 v, as would be expected of course.

Roy

Thank you Roy for taking the time to post. That's exactly what I
was looking for, and answers my questions completely. My
curiousity is satisfied.

Pete

Actually, a "GOOD" RF Ground will exhibit a very LOW Impedance across a broad Frequency Spectrum, and NOT just at any single Frequency.... When designing an RF Grounding System for a particular Site/Antenna System, it is almost as important to know the Frequencies, and Bandwidths, to be transmitted on, as it is to know the practical design of the Antenna itself. Earth Conductivity has a much smaller effect than most folks think.

Oh dear. What does this say about "Artificial RF Grounds?"
For that matter, is a tuned "artificial RF ground" a real  "ground" or part
of the antenna's radiation system?

Pete

its part of the 'system' but radiating or not can be debated.

There are a couple problems when talking about RF Grounds.

You can not equalize the rf voltage over anything that is an
appreciable fraction of a wavelength using any type or combination of
rods, radials, screens, or rings... it just ain't possible. any
ground system other than the fictional 'perfect' ground will have a
pattern of voltage peaks and nulls much like standing waves in 2 or 3
dimensions. therefor you can not call any particular point on the
ground system 'ground' for purposes of voltage measurements... nor can
you trust any particular point to be equal to any other point, so you
can get rf burns while standing on a 'ground' screen and touching a
coax shield or neutral or 'ground' power cable.

The whole purpose of the 'artificial' ground is to force one of the
voltage nulls to be where it will do the most good... if that means
you have problems with rf getting into your computer keyboard, or get
burnt by the mic when you swallow it, you can 'tune' the ground to
cancel out that effect locally... of course that means that there will
be changes in other places that may cause other problems, but at least
you won't get burned.

Now, on to the 'rf ground' as it applies to something you build under
a vertical radiator.... sorry, this will have to wait... just sleep
on currents going up the vertical having to be equal and opposite all
the currents flowing back into the shield side of the coax... no
matter where they come from, and imagine all the chances for currents
to be where you don't want them.

Along with the other use for circulators: To present an impedance match to the reflected wave so that it will not be re-reflected.

> generator to the end of the N(1/2WL) stub and back to the circulator.

It is not clear why you think this verifies something.

Enhancing the details slightly of the generator in the original example: The generator is constructed using the Thevenin model of a source followed by a 50ohm resistor.

With the circulator, there is no re-reflection at the driven end of the line, 50W is dissipated in the circulator resistor and 50W is dissipated in the source resistor.

Without the circulator, there is no re-reflection and nothing is dissipated in the source resistor (and there is no circulator resistor).

The dissipation seems to correlate much more strongly with the circuit design than it does with the magnitude of the "reflected power".

> Please don't insult our intelligence by arguing that is not a steady-
> state condition.

Well you are right, it is not steady-state when there is modulation, but modulation does not affect the examples I have provided.

...Keith

PS: For further understanding, substitute a Norton style generator, then do it again for both kinds of generators but with the end of the line shorted yielding more examples where the "reflected power" does not correlate with the dissipation.

The simple radio do not work without the ground:
http://scitoys.com/scitoys/scitoys/radio/am_transmitter.html

"Without any connection to an antenna or a good ground connection, the
transmitter will only transmit to a receiver a few inches away. To get
better range, clip the ground wire to a good ground, such as a cold water
pipe, and the antenna to a long wire, like the one we used for the crystal
radio."

Is it possible to measure the netto current in the track ground-antenna?

The field emisssion probably works in an antenna: "Field emission can happen
from solid and liquid surfaces, or individual atoms into vacuum or open
air,"
S*

That is the classic answer from the =93reflected power=94 model, but consider the following...

We construct two experiments similar to the above.
The first one:
- a sinusoidal generator that will produce 50W in to 50 ohms
- attach one half wavelength of transmission line
- leave the far end of the transmission line open
- the generator is constructed in the Thevenin style with a voltage source and 50 ohm resistor

The second experiment:
- same as above except there is a circulator between the generator and the line and the circulator is terminated with 50 ohms

Examine experiment 1. After the line settles, a directional wattmeter indicates 50W =93forward power=94 and 50W =93reflected power=94. The current in the voltage source and source resistor is 0 so no energy is dissipated in the source resistor and the voltage source is delivering no energy to the system. The =93reflected power=94 is not being dissipated in the source resistor or voltage source so where is it going. Cecil will offer some explanation where the =93reflected energy=94 is =93redistributed=94 in the other direction as the =93forward energy=94, which =93must=94 be happening since it is not dissipated in the source and it can not be reflected because there is no impedance discontinuity.

Examine experiment 2. After the line settles, a directional wattmeter indicates 50W =93forward power=94 and 50W =93reflected power=94. But with a circulator, the voltage source is delivering 100W, the source resistor is dissipating 50W and the circulator resistor is also dissipating 50W. You offer that the 50W being dissipated in the circulator is the 50W of =93reflected power=94 coming from the line. Presumably then, the 50W of =93forward power=94 is coming from the generator. This agrees numerically since the voltage source is providing 100W and the source resistor is dissipating 50W.

In both experiments, conditions on the line are identical.
There is 50W of =93forward and reflected power=94 indicated.
There is no energy flowing past the end of the line since
it is open circuited.
Because the line is one-half wavelength long, the line
presents an open circuit to the generator (exp 1) or
circulator (exp 2).

In both experiments, the line is presented with a 50 ohm
source impedance, either from the generator or from the
circulator.

What puzzles me then, is how the =93reflected power=94 knows
that in experiment 1, it should stay out of the generator
so that it is not dissipated in the source resistor
but in experiment 2, it should enter the circulator so
that it can be dissipated in the circulator load resistor.

Can you explain how the =93reflected power=94 =93knows=94?

...Keith

Given a 50 ohm source resistor resulting in zero re-reflections, *the dissipation correlates perfectly with the level and type of interference*. I am amazed at the level of ignorance concerning interference and the conservation of energy principle. I studied interference in detail in my 1950's college physics courses including what happens to the energy during interference events. Although Dr. Best didn't realize it, in his QEX Nov/Dec 2001 article on transmission lines, he presented the equations governing energy redistribution associated with interference. What didn't help was his equation of the form:

Ptot =3D 75w + 8.33w =3D 133.33w

which is obviously false. What he left out was the constructive interference term of:

2*SQRT(75w*8.33w) =3D 50w

Given two coherent waves, each associated with a Poynting Vector, when those two waves are superposed, interference will result. I'm sure everyone has seen interference rings and pictures of interference rings where the energy in the interference rings has obviously been redistributed away from a homogeneous power density. The same thing happens in a transmission line and/or at a source, just at longer wavelengths where we cannot "see" them with our eyes.

Constructive interference requires "extra" energy. Superpose two 50 watt coherent waves in phase and the result is a 200 watt wave. Destructive interference has energy left over. Superpose two 50 watt coherent waves 180 degrees out of phase and the result is a zero watt wave. At a source, the source is capable of supplying extra power or throttling back on its power output depending on the level and kind of interference. If one simply takes the time to understand interference, one knows where the energy components go even when there is zero re-reflection.

Given a single traveling wave in a lossless transmission line with a purely resistive characteristic impedance of Z0, the power (joules/second) measured at a point on the line is P=3DV^2/Z0=3DI^2*Z0=3DV*I. This is classic transmission line math no matter which direction the wave is traveling. Superposing two coherent traveling waves cannot create or destroy the energy pre-existing in the two waves, but it can (and often does) redistribute the energy according to the conservation of energy principle. If the total energy in the two superposed waves is different from the sum of the two energy components before superposition, then interference exists and some interference energy has been redistributed in the system. That some people are ignorant of where the constructive interference energy came from or where the destructive interference energy went is not a good reason to deny its existence (which violates the accepted laws of physics).

The thing that makes an interference event so easy to analyze in a transmission line is the fact that the transmission line is essentially one-dimensional. At an impedance discontinuity in a transmission line (away from any active source) if interference exists, the destructive interference in one direction must equal the constructive interference in the other direction. Any other outcome would violate the conservation of energy principle and that is a common occurence on this newsgroup.

In my earlier example, the two results of *(1) reflection* are traveling waves containing ExH power densities:

Pfor1(rho^2) toward the source and

Pref2(rho^2) toward the load

The complimentary transmissions are:

Pfor1(1-rho^2) toward the load and

Pref2(1-rho^2) toward the source

Those two reflections *(2) superpose* with the two complimentary transmissions in each same direction according to the power density equation:

0 =3D Pref1 =3D Pfor1(rho^2) + Pref2(1-rho^2) minus total destructive interference toward the source

Pfor2 =3D Pfor1(1-rho^2) + Pref2(rho^2) plus constructive interference toward the load

When one assumes that reflection is the only phenomenon that can redistribute wave energy, one is ignoring the superposition process which is also known to be perfectly capable of redistributing wave energy. In Roy's food-for-thought example, he designed it so reflections would not exist at the source. That leaves superposition as the phenomenon that is accomplishing the obvious redistribution of energy. It certainly does NOT mean that the laws of physics have been suspended due to the ignorance of the writer.

Here's a simple exercise in phasor superposition. Given two 50w (joules/sec) coherent EM waves traveling in the same direction in Z0=3D50 ohm coax:

1. What is the magnitude of the two voltages? ________

2. If one superposes those two voltages in phase in the Z0=3D50 ohm transmission line, what is the resulting power (joules/sec) in the total wave? ___________

3. If one superposes those two voltages 180 degrees out of phase in the Z0=3D50 ohm transmission line, what is the resulting power (joules/sec) in the total wave? ____________

In #2, if there is no source around, where does the "extra" wave
energy come from?

In #3, if there is no source or sink around, where does the "excess"
wave energy go?

Reflected "power" doesn't know anything. Reflected voltages and currents simply respond to the known laws of physics involving wave reflection and wave superposition, and obey the conservation of energy principle.

In 1, it doesn't stay out of the generator. It is redistributed from the generator back toward the load by superposition associated with *destructive interference) which happens when two superposed coherent waves are between 90 deg and 180 deg out of phase. The entire experiment is set up in a perfect 50 ohm environment so power =3D V^2/50. What you guys are missing is that step which carries the energy along with the voltage, i.e. the voltage (and current) require a certain energy level which is being ignored.

In 2, the source wave never encounters the reflected wave so there is no superposition or interference at the source resistor.

You can add a couple of more configurations. Number 3 could be when the interference between the source wave and the reflected wave occurs and they are less than 90 deg out of phase. More power than the average reflected power plus average load power will be dissipated in the source resistor because of superposition associated with *constructive interference*.

Number 4 could be the special case when the source wave and the reflected wave are 90 degrees out of phase. This is the condition of zero interference (neither destructive nor constructive) and 100% of the average reflected power is dissipated in the source resistor. This is the easiest case to understand because there are no reflections and no interference.

```

> that is 1 wavelength long. A good impedance match results at this frequency and at all higher frequencies. Results are fairly good if the tapered section is as little as 1/2 wavelength long, particularly if the impedance ratio required is less than 2 to 1. It is not worth while to use a tapered section much shorter than 1/2 wavelength, for a taper that is 1/4 wavelength or shorter will give nearly as much reflection as will the abrupt change of impedance at a mismatch. Those frequencies for which the length of the taper is a multiple of a half-wavelength are transmitted with the least reflection. This may be a guide in choosing the length of the taper." The author goes on to state that linear and exponential tapers give practically the same results, and summarizes with a recommendation that a tapered section be between 1/2 and 1 wavelength long at the lowest frequency of use.
>
> Roy Lewallen, W7EL

I've seen essentially the same ... bigger than 1/2 (or 5/8) wavelength works well. BUT... that's for a "good match".. if you're willing to tolerate a "not so good match" I think you can get much shorter.

There's a lot of antenna designs that use this sort of scheme to match, say the 100 ohm impedance of a helix to 50 ohms, over a distance on the order of 1/4 or 1/5 wavelength. Whether it's truly a tapered transmission line or a semi-distributed lumped L and C is probably a good question. Certainly, one could use a string of lumped L/C networks to make a synthetic transmission line that has mechanical length much shorter than 1/2 wavelength. So, when does a series of lumped LCs become a transmission line?

You also see tapered transitions in microstripline all the time, and they're often shorter than 1/2 wavelength. But maybe that's more in the nature of a "distributed matching network" rather than a pure transmission line.

There's a goodly amount of empiricism in both antennas and stripline design. Especially if you're talking about an balanced pair with separation smaller than the diameter/width of the conductor, it's probably not a "simple" transmission line.

```

I saw hints that the application of the tapered line matching section was to a HF off centre fed dipole, and an assumption that as a multiband antenna, it had a feedpoint impedance of close to 200+j0.

Most users of OCF dipole systems are expecting to be able to use the antenna on many bands without an ATU, and accept significant tradeoffs in peformance for that objective.

It is unlikely that the feedpoint impedance of the dipole itself is sufficiently tight to worry too much about the broaband peformance of a tapered line matching section, much less the practicality of constructing low loss tapered two wire lines with Zo approaching 50 ohms.

It is only when a system perspective is taken, that some of the component level discussion seems to be an interesting issue, but poor application.

Owen

well, it works as they say it will only go a few inches because the
antenna is probably only a couple inches long at some low frequency...
once you give it a decent antenna it will work much better.
```

Having built one of these things or very similar (or more properly, my tween daughter did)..

Hook a 6-10 foot long piece of wire to each of the clips and stretch them out and it works pretty well. In my case, we threw a hunk (precision measurement.. probably about 10 ft) of wire over the curtain rod, and laid the other one out across the floor, transmitter sitting on the desk. You could receive it on a standard AM BC radio with a ferrite loopstick antenna at the other end of the house, some 15m/50 ft away.

The idea of using a 1MHz clock oscillator *is* clever. Back in the day, I would have lashed up something with a single transistor and a LC tank.

BTW, the same general idea works pretty well with a 14.318 MHz oscillator..   A 1 meter antenna makes a fine beacon signal right in the 20m band. Of course, you'll ID, operate within your license terms, etc.
  In theory, if you could get it to swing 5V, you could put a couple hundred milliwatts into a dipole, but I don't think they have that much drive available.

I confess I haven't tried AM with the 14.318 oscillator..It probably has some non-zero frequency pulling too.

The "other one out across the floor" works as the chassis.
The chassis is enough for the small power at higher frequencies.
Your phone cell has the chssis (ground) also.

" Transmitters for long and medium wave require good grounding and soil of
high electrical conductivity. Locations at the sea or in river valleys are
ideal, but the flood danger must be considered. Transmitters for UHF are
best on high mountains to improve the range ".

So I look here: http://en.wikipedia.org/wiki/Warsaw_radio_mast

"This technique works by applying a DC ground at a point of minimum
radiofrequency voltage, conducting static charge to ground without
diminishing the radio energy. Static electrical charge can build up to high
values, even at times of no thunderstorm activity, when such tall structures
are insulated from ground."

Would be interesting to know the value of the DC current.

Do you agree that it is the field emission (loss of electrons)?

It certainly depends upon your definition of "power" and that definition is different between pure physics and RF engineering. One of the accepted definitions of "power" in "The IEEE Dictionary" contradicts the definition of "power" given in my college physics book. "The IEEE Dictionary" says that flowing energy passing a fixed measurement point is power, by definition.

If there is anything at all that can be measured, it must necessarily contain energy. If the EM energy is moving, it is power, by IEEE definition. If you disagree, take it up with The IEEE.

So the actual question that needs to be answered is: Does the electromagnetic reflected wave contain energy traveling at the speed of light in the medium? The answer is yes, being photonic in nature, an EM wave must necessarily contain an ExH power density and, consisting of photons, must necessarily be traveling at the speed of light in the medium. The EM wave will continue to travel in the direction of energy flow at the speed of light in the medium until it encounters an impedance discontinuity which causes a reflection and/or interference.

There is really no difference in a forward wave and a reflected wave except for the direction of travel. They both contain an associated ExH power density. One can set up identical signal generators at each end of a transmission line to emulate forward and reflected waves. Which generator yields forward waves and which generator yields reflected waves? It doesn't really matter because direction is only a convention.

because, at least when i do circuit design, i NEVER calculate energy,
and only at the end calculate power if i really need to.  voltage and
current or E and H are the simpler things to handle and totally
sufficient for all circuit analysis, either lumped or distributed.

try listening to the line out from the grundig directly, you may be able to hear it in a set of headphones, or you may need some amplified speakers. see if there is noise there that isn't in the speaker... then turn on the mp3 to record near to the grundig... there is an outside posibility that the mp3 recorder is transmitting a noise that the grundig picks up on that one station's frequency, you may only hear it when the mp3 recorder is connected to the grundig because it is conducted on the cable.

When I said reflection is the first mechanism and superposition is the second mechanism, you said: "... but that [referring to superposition] is NOT a "second' mechanism." The implication seemed clear to me.

Good grief, everyone is free to review what I said and what you said in disagreement. I said reflection is the first mechanism and superposition is the second mechanism. You said superposition is NOT a second mechanism, clearly implying that superposition is the same as the first mechanism which was already defined by me as reflection. Your implication was clearly that reflection and superposition are the same mechanism.

Do you agree that wave reflection can cause a redistribution of wave energy?

Do you agree that superposition can cause a redistribution of wave energy?

Do you agree that wave reflection and wave superposition are two different mechanisms?

If so, you agree with everything I have previously said and are now just blowing smoke. If you misspoke, just admit it. If you misunderstood what I said, just admit it. If you have changed your mind, just admit it. If you still disagree with any of those three statements, please continue the argument that you started in response to my assertion that there exists two mechanisms that can redistribute energy in a transmission line, (1) reflection and (2) superposition.

The subject of this thread is "Where does it go? (mismatched power)",
not "How do I do circuit design?"

Hello friends. good day for you.

I am glad that I have not bothered with my joke, Keith! :>) I was to do some comments to your and Roy posts, but I prefer to ask questions rather than giving personal opinions :>)
....
Please Cecil, friend, do not mention photons and optics (do not bother me, don't worry), I believe you better play your game without such things. I know is like fighting with one arm tied, but I think you can, make an effort :>)

Please Owen explain to me what is "negative power".

In the other thread you said =3D> "The notion that reflected power is simply and always absorbed in the real source resistance is quite wrong. Sure you can build special cases where that might happen, but there is more to it. Thinking of the reflected wave as 'reflected power' leads to some of the misconception.
Then I asked; "remember me what reflected power definition are you using here and expand the sentence idea".
I did not ask for the quoting, I ask (again) for your concept of Reflected Power. I do not sure if you accept (or not) the very notion of reflected power as legitimate. The sentence it is not clear enough to me.

Please, tell us if you accept the idea of two very directive electromagnetic waves from different sources flowing in opposite directions as carring independent energy (with different frequencies at first) and information, and the posibbility that energy be dissipated and/or transmitted by de opposite system and the information being recovered in both ends.
If your answer is yes, then tell us if you conceive such similar system using a same wave guide to simultaneously vinculate both system.

73 - Miguel - LU6ETJ

PS: Roy, friend, take it ease (is OK, or polite say "take it easy?), references to the article were only to complement (bring close?) some useful notions related, mentioning a possible common reference (my english books are few, old and possibly useless as reference nowadays)

You said superposition is NOT a second mechanism, clearly implying that superposition is the same as the first mechanism which was already defined by me as reflection. Your implication was clearly that reflection and superposition are the same mechanism.
>

> Do you agree that wave reflection can cause a redistribution of wave

no. wave reflection causes current and voltage waves to change direction, magnitude, and phase.

>
> Do you agree that superposition can cause a redistribution of wave
> energy?

your observed 'redistribution of wave energy' is a results of superposition of current and voltage waves and then another calculation to convert the sum to power and another calculation to integrate the energy.

>
> Do you agree that wave reflection and wave superposition are two
> different mechanisms?

of course, i've never said otherwise.

The question asked by the original poster is, exactly what happens to the reflected energy? Optical physicists know that a reversal of energy flow direction accompanies the change in direction of the E-field and the B-field which changes the direction of the ExB Poynting vector, i.e. changes the "direction and momentum" of the EM wave according to Eugene Hecht. How can you not know that a voltage/current wave requires energy? How can the voltage and current change direction without the energy changing direction? Does supernatural intervention separate the voltage and current from the ExH energy?

Maybe you should reference, "Fields and Waves ...", by Ramo and Whinnery where they describe the forward and reflected power-density Poynting vectors.

> > Do you agree that superposition can cause a redistribution of wave

Is that a yes or no answer? The same thing happens with light waves in free space where voltage and current are completely irrelevant.

> > Do you agree that wave reflection and wave superposition are two
> > different mechanisms?
>
> of course, i've never said otherwise.

You sure implied otherwise. Why did you argue with me when I said they are two different mechanisms in action to redistribute energy, (1) reflection and (2) superposition? You said superposition is not the second mechanism.

What do I do about people who assert that RF waves possess the ability
to violate the known laws of EM wave physics? It doesn't matter what
the frequency of an EM wave is, it must obey the laws of physics, two
of which are:

1. It cannot exist without a Poynting vector ExH power density.

2. It must necessarily move at the speed of light in the medium.

> what does yours read?

That would most likely be because your wattmeter is AC coupled.
Working
with DC, you need a DC-coupled meter, in which case it would read as
I predicted.

A highly instructive exercise is to examine the schematic for your
directional wattmeter and work out how it implements the expressions
  Vf(t)=3D(V(t)+R0*I(t))/2
  Vr(t)=3D(V(t)-R0*I(t))/2

  Pf=3Davg(Vf(t)*Vf(t)/R0)
  Pr=3Davg(Vr(t)*Vr(t)/R0)
or some equivalent variant using If and Ir.

You will find a voltage sampler, a current sampler, some scaling,
and an addition (or subtraction). If your meter is analog, the
squaring function is usually implemented in the non-linear meter
scale. And the averaging function might be peak-reading or rely
on meter inertia.

>
> no it isn't. =A0in the limit at R->0 =A00V/R still looks like 0 to me.

When computing the intermediate results using superposition, you
have the full battery voltage in to 0 ohms. First the battery on
the left, then the one on the right, and then you add the two
currents to get the total current. 0 is always the total, but

the intermediate results can go to infinity if you connect
the two batteries directly in parallel.

> your post is based on an incorrect premise.

Then what are the equations for computing forward and reflected waves
and 'power'? That is where I started. Is that the premise you consider
to be incorrect?

Do follow through the arithmetic in the previously provided examples
and see if you can find any faults. Point me to any errors and I will
gladly reconsider my position.

If not, perhaps it is time for you to start questioning your
assumptions.

...Keith

mine is dc coupled... still nothing.  please provide the schematic or
model number for the one you use to get such a reading.

there is no battery on the right, unless you have changed the case again. i thought we were doing the open circuit coax with the dc source on one end.

but even if you have the case above and connect another 100v battery on the open end of the line there will be no current flowing back as there is no voltage difference to drive it.

yep, your 'waves' don't include the proper term to make them propagating waves that satisfy maxwell's equations... so they can't be real... so your initial premise is incorrect.

my assumptions are perfectly valid... it is yours that are flawed from the very beginning.

One does, however, usually require that the more sophisticated model continue to provide the correct answer for the simpler problems that could be solved in another way.

And it does here as well, though the answers make some uncomfortable.

> > Still, I observe that you have discovered no errors in the exposition.
>
> I have not wasted my time time trying to discover any errors. In a
> nutshell, what new knowledge have you presented?

Well, at least you continue to read the posts, so perhaps there is some slim hope, but I am not holding my breath.

As for me, I have learned a lot from your postings since I first encountered them circa 1994. Back then, I was not so knowledgeable about transmission lines and I was trying to decide who was right. You posted well thought out, convincing arguments and I found myself switching from side to side. Reflected waves heat finals, no they don't, yes they do, ... but eventually I learned. Then I continued to read your posts, visited your web site and studied your arguments. The challenge was to discover where you had gone wrong. Occasionally I would think up a suitable counter example and offer it to you, but, even then, you refused to look at examples that might threaten your beliefs. So I no longer post with any expectation that you might be persuaded.

Mostly now I post to ensure that a view other than yours is voiced to help prevent those who are not yet sure from being sucked in to your vortex.

Anyhow, I suggest you read my examples and find the flaws, for that is the surest way to convince me that I am wrong. And don't just post other examples that support your position, for it only takes one counter-example to disprove a hypothesis, no matter how many examples are in agreement. And don't reject simple DC examples because
they lead to uncomfortable answers for it is by examining the examples
that do not support your hypotheses that you will learn, not by sticking
just with the ones that do.

...Keith

Oh my. Could you kindly provide the schematic or a reference? Before
posting I spent an hour searching my library and the web for the
circuit
for a dc-coupled directional wattmeter and was unsuccessful.

Nothing prevents one from being constructed. That one is not readily
available should not prevent you from using the equations that they
implement and then predicting the DC behaviour of the line.

No. I was referring to the simple DC circuit with two batteries and
a resistor. I was pretty sure that was your referent when you used
"R->0".

I understand that you have not found any flaws in my exposition,
except that you are still uncomfortable with the results. It is
possible to overcome this.

And I re-iterate the value of studying your directional wattmeter's
schematic, especially if it is DC-coupled.

...Keith

You have fallen in to the same trap that you did with circulators.
When you introduce a circulator in to the transmission line, you
change the experiment and you get certain results. The circulator
provides some numerology that appears to support the hypothesis
of 'reflected energy' being real. The same with looking for
"missing energy" (note they even quote it) with a beamsplitter.
The beamsplitter reveals what is happening at the beamsplitter,
not what is happening at points between the two beamsplitters.

Just like a circulator.

...Keith

he is even more hopeless than most, first he determines there are
forward and reflected waves when a dc source has charged the line,
then he rejects circulators and beamsplitters that obviously work
because of the waves.  so dc waves exist, but rf and optical waves
don't.  thats a unique viewpoint.

It appears that you are a masochist [to yourself] or a sadist [to the kid you had use a sledgehammer !!! There is a much, much easier device, to place ground rods in place. It's called a 'Water Drill'. You use typically 3/4" galvanized steel pipe of the appropriate length {couple lengths together, as needed}, add a 1' > 2' section at a right angle to the main vertical length, for rotational/insertion/extraction leverage. On the end of the short piece, add a female hose [with a water shut-off] to pipe adapter. On the vertical pipe, add a older style adjustable brass spray nozzle. You usually want a forceful stream. Simply place the nozzle end where you desire to begin a hole for the ground rod. Turn on the water (wear a raincoat/wetsuit, if you like), and apply slight downward pressure. You may need to alternately extract and reinsert, to allow dirt, from the hole being drilled, to escape.

This procedure, very possibly, may not work in VE6 land; in the wintertime. Where I live, I can drill a hole in usually less than 5 minutes, and drop in the ground rod shortly thereafter.

I got a new miniplug cable, a coiled one and that
seems to have fixed it. Odd that the first one only picked up noise on
that one station.

thx,

Hi

I'm after some FB-31-1020 ferrite rings to go on my Hexbeam.

Any one know where I can get some from here in the UK or is there an
equivalent I can get?

Thanks

Since no one stepped up who has the experience and knowledge, I will
offer an opinion:

Further would be better but the more practical decision will be based
on what is reasonable and maintainable.

Everything is a compromise!

I have plans for a very good 6 element beam which is 15.53 feet from reflector to D4. I could scale it to the element taper you have if needed.

It will not be a direct connect however, as those are almost never optimal designs for gain, F/B or pattern. They are optimized to be 50 ohms with the rest subservient to that. Most of the designs I have would be around 22 ohms so this one is probably in that area. A gamma match is easy to make.

Sorry, I should have looked before leaping, it's 5 elements on 15.5 feet.

There are at least 3 reasons to use some kind of a matching network.
```

1. impedance transformation - usually the feedpoint impedance of a simple dipole in a yagi is not near 50 ohms so the matching system gives you an easy way to adjust that.
2. it is often easier to build an aluminum element without a center insulator and feed it with something like a gamma or T match.
3. to keep current off the feedline shield you need to go from the unbalanced coax to a balanced dipole feedpoint. gamma matches and others do that transformation for you.

```

I have an old 2-meter Ringo Ranger on top of the tower that has not been used for some time. I wonder how it will do for six meters?

None of my SWR boxes cover VHF so may have to just give it try and see what happens.

Wish me luck

It was a good idea that DID NOT work.  The SWR as shown
on rig's s-meter was terrible and I could tell it was not  hearing
as well as the fan dipole.

I am in agreement with all your points. [Not that I am any kind of authority!]

Many years back I purchased and installed a Cushcraft A3S tri band beam with the 40 Meter option. The decision was based on past experience with Cushcraft products.

When I assembled it I was disappointed to find it did not have a gamma match! Instead it got by with a direct connection to the driven element with the 50 ohm line. Then it used a jury rig device called a "choke balun" to keep the RF where it ought to be... It reminded me of the Gotham Vertical (Google it!) that so many of us fell for way back when. I assembled and installed it according to the instructions any way. Much to my surprise, it worked great! I have been very happy with it.

That led to my taking the ARRL Antenna course and buying the EZNEC program.

Some things I model I can make work and some I cannot.
Some things work I cannot model.
I have concluded that direct connection and gamma matches both work well.

My cumulative experience is that it is difficult to beat the commercial products at their game.

OTH, the study and construction of antennas has become one of my favorite recreational pastimes!

Just curious if this has ever been done? I'm thinking about
putting up a 90 foot dipole feed with homemade open wire
line. I'd like to bring it into the shack using paralled runs

of LMR-400 cable, since the final 25 feet is via 3" electrical
conduit that also has rotor and other cables.

I believe the parallel cables with give me a 100 ohm impedance.
The open wire will be using #10 with homemade spreaders,
I'm going to try for 600 ohms at the feedpoint. I was wondering
if tapering the spacing on the feedline would give me a smoother
impedance where the open wire, arrestor, and twin coax arrange-
meet?

define "rf ground".

Something that provides a counterpoise for an unbalanced feedline
situation that doesn't result in RF energy being wasted to heat
earthworms, soil, etc. and radiates RF energy efficiently.

My "ARRL Antenna Book", 20th edition, has a section on "Tapered
Lines". They say it should be at lease one wavelength on the lowest
frequency of operation. They give an "air insulated" formula for such
a design.

Cushcraft prided themselves on building antennas with a DC resistance of 0 ohms.

In plain English they were static disipators. At their design frequency they had an impedance of 50 ohms.

When I lived in Philly, we had a sever lightening problem. Whenever there were lightening storms there were nearby strikes with all sorts of expensive EMP problems.

When I put up a cushcraft 2m beam (the 11 element vertical polarization on the same beam as an 11 element horizontal one) with proper gounding they all "went away". I wonder if our neighbors suddenly noticed next spring that the lightening had come back :-)

Geoff.

the ground radiates? that's interesting.

so the raised radials on my 80m 4-square would be considered an rf
ground?

Yes, it has been done. Jasik's "Antenna Engineering Handbook" discusses tapered lines in section 31.4. You can also find a discussion of tapered-line matching in Laport's "Radio Antenna Engineering" in section 4.4.8 (this book is available as a free PDF download).

In your application, though, I'm not sure why you would want to bother. Traditionally, tapered lines are used as part of a matching network, making a transition between two known resistive impedances (e.g. transmitter and antenna).

That's not really the situation you seem to be setting up. You are (I presume) setting up a single doublet, to be used at multiple frequencies, with wildly varying impedances at the antenna feedpoint. You're then coming back to the shack with a high-impedance feedline (which has relatively low losses even at the high SWRs it'll be operating at), and then matching the impedance in the shack with a good transmatch-and-balun.

In a setup like this, the characteristic impedance of the open-wire line isn't particularly critical.. because it'll almost never be a close match to what the antenna is presenting at any given frequency. 600 ohms is a common feedline impedance... but no matter what impedance you choose here, it's unlikely to be a close match to the antenna under actual operating conditions. As a result, the impedance you actually "see" looking up into the lower end of the open-wire line won't be 600 ohms (if untapered) or 100 ohms (if tapered down close

together). Rather, it'll be the feedpoint impedance of the antenna at
the frequency in question, transformed by the feedline (tapered or
not). You could calculate it, knowing the antenna's feedpoint
impedance (e.g. from modeling it in NEC2) and the length and Z of the
feedline... but it isn't likely to be close to a convenient pure
resistance except by lucky chance!

Hence, there's no real need to "match" the lower Z of the parallel-
coax segment (100 ohms nominal) to Z of the open-wire line, since the
latter value isn't actually what you'd have to match to!

Now, if you're planning to operate at a specific single frequency, you
could perhaps utilize a tapered open-wire line as part of a tuned
matching setup... in effect, designing the taper for that one antenna
and frequency, in order to present a more convenient impedance to your
transmitter's matching network (e.g. your external wide-range
transmatch). However, optimizing the system in this way, for one
specific frequency, might well make the antenna-and-feedline a
harder load for you to match in the shack at other frequencies.

A gamma rod is the easiest thing in the world to build...people who
are scared of 'em just don't understand 'em. :)

Based on my personal experience trying to replace the inside shack portion of 600 ohm open feed line with two parallel pieces of RG-213 about 8 ft. long. The coax sections will effectively kill the use of your dipole on any of the higher frequencies. As I remember, the antenna was usable up through 10 meters , but after putting in the coax, I couldn't tune the system above 20 meters.

My antenna is a full sized 160 meter horizontal loop in the form of a trapazoid, almost a square, up at 35 ft. Fed in one corner with 600 ohm open wire,125 ft. long. The feedline comes into the house (mfg home with aluminum siding) using two Birnbach feed through insulators. Then to a DPDT antenna switch to ground the system during thunder storms, and finally about 6 ft of 600 ohm feed line to the balun in the Dentron MT-3000 tuner.

I think the problem with using the double coax is the very large capacitance it adds to the feed line, effectively becoming a low pass filter. Could be mistaken about the cause, but not the symptoms. I have actually used the system to make some local 6 meter contacts.

Try it anyway, but be prepared to go all the way to the shack with your 600 ohm feed line.

Paul, KD7HB

Yes, but will the configuration have the benefits you think? See
http://www.vk1od.net/transmissionline/stcm/index.htm for more info.

> The open wire will be using #10 with homemade spreaders,
> I'm going to try for 600 ohms at the feedpoint. I was wondering

What is 600 ohms, the feed line or the antenna.

If the feed line operates at high VSWR, it doesn't matter a lot what Zo
is. Further, that using tapered lines as a broadband impedance match
requires that the taper section is quite long wrt wavelength.

> if tapering the spacing on the feedline would give me a smoother
> impedance where the open wire, arrestor, and twin coax arrange-
> meet?

I cannot reconcile the 90' dipole and 600 ohms from the little
information you have given.

Your post is very short on information, so it is entirely a guessing game.

Owen

Well Dick, you only asked for positive responses, and you go none... so no surprises.

The matching arrangement on the Ringo is a quite narrow band one, so you should expect that it will not work well on 6m.

It is not uncommon to hear of people on HF using a 11m end fed half wave with narrowband matching (ie similar to the Ringo) on the lower bands (eg 7MHz) with the 'assistance' of an ATU. I quote 'assistance' because the ATU does assist in obtaining a good VSWR for the transceiver, but probably converts most of the transmitter to heat. A good example of the failure of an entirely VSWR focused approach.

An ATU can hide a multitude of sins.

Owen

The coax is, and always is a transmission line, and at the length you described cannot be approximated well as a shunt capacitance.

What you have is a cascade of two line sections, one of say 600 ohms, then one of 100 ohms, and each is probably operating with standing waves, so there is impedance transformation.

To illustrate, lets say your feedpoint at 3.6MHz with a certain loop antenna was 100+j0, and you had say 30m (100') of 600 ohm open wire, the impedance looking into that would be around 240-j675. If you feed that with say 6m (20') of LMR400 twin, then input Z would be around 60+j260 and loss would be about 40%.

The synthesised shielded pair is relatively lossy, and low Zo. Most people use this configuration thinking that the shielding prevents external fields from common mode current, but they are quite wrong. See http://www.vk1od.net/transmissionline/stcm/index.htm .

Though the traditional approach has been to use a 4:1 voltage balun at the rig to feed these things, there is good argument to use a 1:1 Guanella balun (current balun), and it can be located outside the shack and inboard shield effectively grounded to deal with common mode current. You still need to minimise the length of coax operated at high VSWR, and it would not be necessarily absurd to think about low loss coax.

Approximating coax as a shunt capacitance might be reasonably accurate for some applications at audio frequencies, but it is probably not for most RF applications.

Owen

Yes, but determining where the reflected energy goes is the title of
this thread. My method shows where the reflected energy goes and yours
does not! That's the entire point.

It's simply the relative phase angle between the forward voltage and
reflected voltage at the source resistor. I trust that you can manage
that without my help.

ah, but it does... it gives the exact same results but without all the
power manipulations. the point is, in sinusoidal steady state you can
calculate the impedance seen by the source and get all those same
results much simpler than trying to track forward and reflected
powers. and if you really want to know the source and load powers
they are easy enough to get as i showed.

ah, so you do have to calculate the voltages, which would requires two
transformations of the length of the coax plus calculating the
magnitude and angle of the complex reflection coefficient then adding
them all up.  still sounds like more work than necessary.

Hello all

If I do not make any mistake, my numbers agree with yours Cecil, it is
a pleasure (my procedure was the old plain and simple standard) :>)
I know, 1000 examples probe nothing, only one popperianists man can
bring a black swan at any time and falsify the induction :>). but now
seems more clear to me you have a predictive model that render
identical numbers of my classical one, at least in basic tests, it is
a step forward to better considerate your efforts and with goodwill
begin to establish basic points of agreement.
I recognize it is a more simple approach the classic method (as said
K1TTT) to me too, but also I think not always one good method or model
it is more convenient to understand another useful view of phenomena.
Phasorial solutions are good, practical and likely complete electric
solutions but in my opinion they do not married very well with other
more general electromagnetic and physics models (wave guides perhaps?
I have not experience); unification has its advantages too (However my
favourite answer was definitely the Roy's one in the fourth post of
the thread, hi hi...)

73 - Miguel - LU6ETJ

PS: Owen do not be upset with me :>) most of my available newsgroup
time it is spent in translate to english without flaws that may induce
to misinterpretations (all of you are very demanding with precise
wording and exact definitions), one mistake and I will need three or
four painly translations more to clarify :>D

Today I tested your interesting formula with a Half wave 50 ohms TL,
loaded with 100 and 25 ohms respectively. Vs=3D100 Vrms, Rs=3D50 ohm give
2:1 VSWR. In both cases then Pf 50 W, Pr=3D5.5 W, Pnet=3D44.4 W. Giving
Vf=3D50 V and Vr=3D16,6 V aprox. for both loads.
I am using (Pf=3DPnet / (1-Rho^2) and Pr=3DPnet / ((1/1/Rho^2) -1) formula
which not gives different sign to Vr, in such case applying to
PRs=3D(((Vs/2)-Vr)^2)/Rs =3D> ((50/2)-16.66)^2/50. I get PRs=3D22,2 with

both loads because the sign of Vf (always +) from simple Pr and Pf
formulas, changing the sign of Pr render Rs=3D88,8 W for Prs (OK).

I have in my disk a very descriptive, advisable and friendly article
downloaded from: http://www.ittc.ku.edu/~jstiles/622/handouts/Transmission_=
Lines_package.pdf

In page number 88 there is a agreement with your formula in "Is zo of
aa HF ham tx typycally 50+j0?".

I stand corrected. In the special case of Rs = Z0, the steady state forward voltage and therefore "forward power" become independent of the transmission line length and load impedance, just as you said and show in your analysis.

But this isn't true in the general case where Rs isn't equal to Z0. In the general case, the forward voltage is

```
   Vf = Vfi * exp(-j*theta) / (1 - Gs*Gl*exp(-j*2*thetal))
```

```
where Gs = reflection coefficient at the source looking back from the
            line = (Zs - Z0)/(Zs + Z0)
       Gl = reflection coefficient at the load = (Zl - Z0)/(Zl + Z0)
       theta = distance along the line from the source end
       thetal = length of the line in radians
       Vfi = initial forward voltage = Vs * Z0 / (Zs + Z0)
```

At the input end of the line, theta = 0 so

```
   Vf1 = Vfi / (1 - Gs*Gl*exp(-j*2*thetal))
```

and the reverse voltage at the input is

Vr1 = Gl * Vf1 * exp(-j*2*thetal)

Note that although Vf is a function of Gs, reflected voltage Vr is also a function of Gs and their ratio is not. So VSWR and Pf/Pr don't depend on Gs. But the general equation for Vf does include line length and Z0 as well as both source and load Z.

In the example I posted earlier (Transmitter power 100 watts, load Z = 50 + j0, line length 1/2 wavelength), no mention was made of the source impedance, only the power being delivered by the transmitter, which was the same for both cases since the impedance seen by the transmitter didn't change. In the first case, where Z0 = Zl = 50 + j0, the forward power on the line was 100 watts and reverse power was zero. In the second case, the line Z0 was changed to 200 ohms. This caused an increase in forward power to 156.25 watts (calculated from VSWR). From these we can infer that the forward voltage increased by a factor of 2.5 from sqrt(100 * 50) = 70.71 Vrms to sqrt(156.25 * 200) = 176.8 Vrms. Let's see if this agrees with the equations.

When the line is a half wavelength long, thetal = pi, so the equation for Vf1 simplifies to:

Vf1 (half wavelength line) = Vfi / (1 - Gs*Gl)

Expanding Vfi, Gs, and Gl results in

Vf1 (half wavelength line) = Vs * (Z0 + Zl)/(2 * (Zs + Zl))

Various combinations of Vs and Zs can give us the 100 assumed watts, but we don't need to specify any specific values. Leaving Vs and Zs as unknown constants and Zl as fixed, we can find the ratio for two different values of Z0:

Vf1 = Vs * (Z01 + Zl)/(2 * (Zs + Zl))
Vf2 = Vs * (Z02 + Zl)/(2 * (Zs + Zl))

Vf2/Vf1 = (Z02 + Zl)/(Z01 + Zl)

In the example, case 1 had Z0 = Z01 = 50; case 2 had Z0 = Z02 = 200, and Zl was 50 for both. So Vf2/Vf1 = (200 + 50)/(50 + 50) = 2.5, which agrees with the calculation based on VSWR.
